

TMS570LS12x/11x 16/32-Bit RISC Flash Microcontroller

Technical Reference Manual

Literature Number: SPNU515B

April 2015

| | |
|---|------------|
| Preface | 95 |
| 1 Introduction | 98 |
| 1.1 Designed for Safety Applications | 99 |
| 1.2 Family Description | 99 |
| 1.3 Endianism Considerations | 102 |
| 1.3.1 TMS570: Big Endian (BE32) | 102 |
| 2 Architecture | 103 |
| 2.1 Introduction | 104 |
| 2.1.1 Architecture Block Diagram | 104 |
| 2.1.2 Definitions of Terms | 105 |
| 2.1.3 Bus Master / Slave Access Privileges | 107 |
| 2.2 Memory Organization | 108 |
| 2.2.1 Memory-Map Overview | 108 |
| 2.2.2 Memory-Map Table | 109 |
| 2.2.3 Flash on Microcontrollers | 113 |
| 2.2.4 On-Chip SRAM | 115 |
| 2.3 Exceptions | 120 |
| 2.3.1 Resets | 120 |
| 2.3.2 Aborts | 120 |
| 2.3.3 System Software Interrupts | 122 |
| 2.4 Clocks | 123 |
| 2.4.1 Clock Sources | 123 |
| 2.4.2 Clock Domains | 124 |
| 2.4.3 Low Power Modes | 127 |
| 2.4.4 Clock Test Mode | 129 |
| 2.4.5 Safety Considerations for Clocks | 130 |
| 2.5 System and Peripheral Control Registers | 133 |
| 2.5.1 Primary System Control Registers (SYS) | 133 |
| 2.5.2 Secondary System Control Registers (SYS2) | 186 |
| 2.5.3 Peripheral Central Resource (PCR) Control Registers | 193 |
| 3 Power Management Module (PMM) | 208 |
| 3.1 Overview | 209 |
| 3.1.1 Main Features of the Power Management Module (PMM) | 209 |
| 3.1.2 Block Diagram | 209 |
| 3.2 Power Domains | 211 |
| 3.3 PMM Operation | 212 |
| 3.3.1 Power Switch | 212 |
| 3.3.2 Power Domain State | 212 |
| 3.3.3 Default Power Domain State | 212 |
| 3.3.4 Disabling a Power Domain Permanently | 212 |
| 3.3.5 Changing Power Domain State | 212 |
| 3.3.6 Reset Management | 213 |
| 3.3.7 Diagnostic Power State Controller (PSCON) | 213 |
| 3.3.8 PSCON Compare Block | 213 |
| 3.4 PMM Registers | 215 |

| | | |
|----------|---|------------|
| 3.4.1 | LOGICPDPWRCTRL0 Register (Offset = 0h) [reset = X] | 216 |
| 3.4.2 | MEMPDPWRCTRL0 Register (Offset = 10h) [reset = X] | 218 |
| 3.4.3 | PDCLKDIS Register (Offset = 20h) [reset = X] | 219 |
| 3.4.4 | PDCLKDISSET Register (Offset = 24h) [reset = X] | 220 |
| 3.4.5 | PDCLKDISCLR Register (Offset = 28h) [reset = X] | 221 |
| 3.4.6 | LOGICPDPWRSTAT0 Register (Offset = 40h) [reset = X] | 222 |
| 3.4.7 | LOGICPDPWRSTAT1 Register (Offset = 44h) [reset = X] | 223 |
| 3.4.8 | LOGICPDPWRSTAT2 Register (Offset = 48h) [reset = X] | 224 |
| 3.4.9 | LOGICPDPWRSTAT3 Register (Offset = 4Ch) [reset = X] | 225 |
| 3.4.10 | MEMPDPWRSTAT0 Register (Offset = 80h) [reset = X] | 226 |
| 3.4.11 | MEMPDPWRSTAT1 Register (Offset = 84h) [reset = X] | 228 |
| 3.4.12 | GLOBALCTRL1 Register (Offset = A0h) [reset = 0h] | 230 |
| 3.4.13 | GLOBALSTAT Register (Offset = A8h) [reset = 1h] | 231 |
| 3.4.14 | PRCKEYREG Register (Offset = ACh) [reset = 0h] | 232 |
| 3.4.15 | LPDDCSTAT1 Register (Offset = B0h) [reset = 0h] | 233 |
| 3.4.16 | LPDDCSTAT2 Register (Offset = B4h) [reset = 0h] | 234 |
| 3.4.17 | MPDDCSTAT1 Register (Offset = B8h) [reset = 0h] | 235 |
| 3.4.18 | MPDDCSTAT2 Register (Offset = BCh) [reset = 0h] | 236 |
| 3.4.19 | ISODIAGSTAT Register (Offset = C0h) [reset = 0h] | 237 |
| 4 | I/O Multiplexing and Control Module (IOMM) | 238 |
| 4.1 | Overview | 239 |
| 4.2 | Main Features of I/O Multiplexing Module (IOMM) | 239 |
| 4.3 | Control of Multiplexed Outputs | 239 |
| 4.4 | Control of Multiplexed Inputs | 240 |
| 4.5 | Control of Special Multiplexed Options | 241 |
| 4.5.1 | Control of SDRAM clock (EMIF_CLK) | 241 |
| 4.5.2 | Control for other EMIF Outputs | 241 |
| 4.5.3 | Control for Fast Mode for Synchronous and Asynchronous EMIF | 242 |
| 4.5.4 | Control of Ethernet Controller Mode | 242 |
| 4.5.5 | Control of ADC Trigger Events | 242 |
| 4.5.6 | Control for ADC Event Trigger Signal Generation from ePWMx Modules | 243 |
| 4.5.7 | Control for Generating Interrupt Upon External Fault Indication to N2HETx | 245 |
| 4.5.8 | Control for Enabling Clocks to ePWMx Modules | 245 |
| 4.5.9 | Control for Enabling Clocks to eCAPx Modules | 246 |
| 4.5.10 | Control for Enabling Clocks to eQEPx Modules | 246 |
| 4.5.11 | Control for Synchronizing Time Bases for All ePWMx Modules | 246 |
| 4.5.12 | Control for Synchronizing all ePWMx Modules to N2HET1 Module Time-Base | 247 |
| 4.5.13 | Control for Input Connections to ePWMx Modules | 248 |
| 4.5.14 | Control for Input Connections to eCAPx Modules | 249 |
| 4.5.15 | Control for Input Connections to eQEPx Modules | 249 |
| 4.6 | Safety Features | 250 |
| 4.6.1 | Locking Mechanism for Memory-Mapped Registers | 250 |
| 4.6.2 | Error Conditions | 250 |
| 4.7 | IOMM Registers | 251 |
| 4.7.1 | REVISION_REG Register (Offset = 0h) [reset = 4E840102h] | 252 |
| 4.7.2 | ENDIAN_REG Register (Offset = 20h) [reset = 0h] | 253 |
| 4.7.3 | KICK_REG0 Register (Offset = 38h) [reset = 0h] | 254 |
| 4.7.4 | KICK_REG1 Register (Offset = 3Ch) [reset = 0h] | 255 |
| 4.7.5 | ERR_RAW_STATUS_REG Register (Offset = E0h) [reset = 0h] | 256 |
| 4.7.6 | ERR_ENABLED_STATUS_REG Register (Offset = E4h) [reset = 0h] | 257 |
| 4.7.7 | ERR_ENABLE_REG Register (Offset = E8h) [reset = 0h] | 258 |
| 4.7.8 | ERR_ENABLE_CLR_REG Register (Offset = ECh) [reset = 0h] | 259 |
| 4.7.9 | FAULT_ADDRESS_REG Register (Offset = F4h) [reset = 0h] | 260 |

| | | |
|----------|---|------------|
| 4.7.10 | FAULT_STATUS_REG Register (Offset = F8h) [reset = 0h] | 261 |
| 4.7.11 | FAULT_CLEAR_REG Register (Offset = FCh) [reset = 0h] | 262 |
| 4.7.12 | PINMMR_0 to PINMMR_47 Register (Offset = B10h to BCCh) [reset = 1010101h] | 263 |
| 4.8 | Output Multiplexing and Control | 264 |
| 5 | F021 Flash Module Controller (FMC) | 266 |
| 5.1 | Overview | 267 |
| 5.1.1 | Features | 267 |
| 5.1.2 | Definition of Terms | 267 |
| 5.1.3 | F021 Flash Tools | 268 |
| 5.2 | Default Flash Configuration | 268 |
| 5.3 | SECEDED | 269 |
| 5.3.1 | SECEDED Initialization | 269 |
| 5.3.2 | ECC Encoding | 270 |
| 5.3.3 | Syndrom Table: Decode to Bit in Error | 271 |
| 5.3.4 | Syndrom Table: An Alternate Method | 272 |
| 5.4 | Memory Map | 273 |
| 5.4.1 | Location of Flash ECC Bits | 273 |
| 5.4.2 | OTP Memory | 274 |
| 5.5 | Deliberate ECC Errors for FMC ECC Checking | 276 |
| 5.6 | Power On, Power Off, and Reset Considerations | 277 |
| 5.6.1 | Error Checking at Power On | 277 |
| 5.6.2 | Flash Integrity when Reset while Programming or Erasing | 277 |
| 5.6.3 | Flash Integrity at Power Off | 277 |
| 5.7 | Emulation and SIL3 Diagnostic Modes | 277 |
| 5.7.1 | System Emulation | 277 |
| 5.7.2 | Diagnostic Mode | 277 |
| 5.7.3 | Diagnostic Mode Summary | 280 |
| 5.7.4 | Read Margin | 282 |
| 5.8 | Control Registers | 282 |
| 5.8.1 | Flash Option Control Register (FRDCNTL) | 284 |
| 5.8.2 | Flash Error Detection and Correction Control Register 1 (FEDACCTRL1) | 285 |
| 5.8.3 | Flash Error Correction and Correction Control Register 2 (FEDACCTRL2) | 287 |
| 5.8.4 | Flash Correctable Error Count Register (FCOR_ERR_CNT) | 287 |
| 5.8.5 | Flash Correctable Error Address Register (FCOR_ERR_ADD) | 288 |
| 5.8.6 | Flash Correctable Error Position Register (FCOR_ERR_POS) | 289 |
| 5.8.7 | Flash Error Detection and Correction Status Register (FEDACSTATUS) | 290 |
| 5.8.8 | Flash Un-Correctable Error Address Register (FUNC_ERR_ADD) | 293 |
| 5.8.9 | Flash Error Detection and Correction Sector Disable Register (FEDACSDIS) | 294 |
| 5.8.10 | Primary Address Tag Register (FPRIM_ADD_TAG) | 295 |
| 5.8.11 | Duplicate Address Tag Register (FDUP_ADD_TAG) | 295 |
| 5.8.12 | Flash Bank Protection Register (FBPROT) | 296 |
| 5.8.13 | Flash Bank Sector Enable Register (FBSE) | 296 |
| 5.8.14 | Flash Bank Busy Register (FBBUSY) | 297 |
| 5.8.15 | Flash Bank Access Control Register (FBAC) | 298 |
| 5.8.16 | Flash Bank Fallback Power Register (FBFALLBACK) | 299 |
| 5.8.17 | Flash Bank/Pump Ready Register (FBPRDY) | 300 |
| 5.8.18 | Flash Pump Access Control Register 1 (FPAC1) | 301 |
| 5.8.19 | Flash Pump Access Control Register 2 (FPAC2) | 302 |
| 5.8.20 | Flash Module Access Control Register (FMAC) | 302 |
| 5.8.21 | Flash Module Status Register (FMSTAT) | 303 |
| 5.8.22 | EEPROM Emulation Data MSW Register (FEMU_DMSW) | 305 |
| 5.8.23 | EEPROM Emulation Data LSW Register (FEMU_DLSW) | 305 |
| 5.8.24 | EEPROM Emulation ECC Register (FEMU_ECC) | 306 |

| | | |
|----------|---|------------|
| 5.8.25 | EEPROM Emulation Address Register (FEMU_ADDR) | 307 |
| 5.8.26 | Diagnostic Control Register (FDIAGCTRL) | 308 |
| 5.8.27 | Uncorrected Raw Data High Register (FRAW_DATAH) | 310 |
| 5.8.28 | Uncorrected Raw Data Low Register (FRAW_DATAH) | 310 |
| 5.8.29 | Uncorrected Raw ECC Register (FRAW_ECC) | 311 |
| 5.8.30 | Parity Override Register (FPAR_OVR) | 312 |
| 5.8.31 | Flash Error Detection and Correction Sector Disable Register (FEDACSDIS2) | 313 |
| 5.8.32 | FSM Register Write Enable (FSM_WR_ENA) | 314 |
| 5.8.33 | FSM Sector Register (FSM_SECTOR) | 314 |
| 5.8.34 | EEPROM Emulation Configuration Register (EEPROM_CONFIG) | 315 |
| 5.8.35 | EEPROM Emulation Error Detection and Correction Control Register 1 (EE_CTRL1) | 316 |
| 5.8.36 | EEPROM Emulation Error Correction and Correction Control Register 2 (EE_CTRL2) | 318 |
| 5.8.37 | EEPROM Emulation Correctable Error Count Register (EE_COR_ERR_CNT) | 318 |
| 5.8.38 | EEPROM Emulation Correctable Error Address Register (EE_COR_ERR_ADD) | 319 |
| 5.8.39 | EEPROM Emulation Correctable Error Position Register (EE_COR_ERR_POS) | 320 |
| 5.8.40 | EEPROM Emulation Error Status Register (EE_STATUS) | 321 |
| 5.8.41 | EEPROM Emulation Un-Correctable Error Address Register (EE_UNC_ERR_ADD) | 322 |
| 5.8.42 | Flash Bank Configuration Register (FCFG_BANK) | 323 |
| 6 | Tightly-Coupled RAM (TCRAM) Module | 324 |
| 6.1 | Overview | 325 |
| 6.1.1 | B0TCM and B1TCM Connection Diagram | 325 |
| 6.1.2 | Main Features | 325 |
| 6.2 | RAM Memory Map..... | 326 |
| 6.3 | Safety Features | 327 |
| 6.3.1 | Support for Cortex-R4F CPU's Single-Error-Correction Double-Error-Detection (SECEDED) | 327 |
| 6.3.2 | Support for Cortex-R4F CPU's Address and Control Bus Parity Checking | 328 |
| 6.3.3 | Redundant Address Decode | 328 |
| 6.4 | TCRAM Auto-Initialization | 328 |
| 6.5 | Trace Module Support | 329 |
| 6.6 | Emulation / Debug Mode Behavior | 329 |
| 6.7 | Control and Status Registers..... | 329 |
| 6.7.1 | TCRAM Module Control Register (RAMCTRL) | 330 |
| 6.7.2 | TCRAM Module Single-Bit Error Correction Threshold Register (RAMTHRESHOLD) | 331 |
| 6.7.3 | TCRAM Module Single-Bit Error Occurrences Counter Register (RAMOCCUR) | 332 |
| 6.7.4 | TCRAM Module Interrupt Control Register (RAMINTCTRL) | 332 |
| 6.7.5 | TCRAM Module Error Status Register (RAMERRSTATUS) | 333 |
| 6.7.6 | TCRAM Module Single-Bit Error Address Register (RAMSERRADDR)..... | 334 |
| 6.7.7 | TCRAM Module Uncorrectable Error Address Register (RAMUERRADDR) | 335 |
| 6.7.8 | TCRAM Module Test Mode Control Register (RAMTEST)..... | 336 |
| 6.7.9 | TCRAM Module Test Mode Vector Register (RAMADDRDECVECT) | 337 |
| 6.7.10 | TCRAM Module Parity Error Address Register (RAMPERRADDR) | 337 |
| 7 | Programmable Built-In Self-Test (PBIST) Module | 338 |
| 7.1 | Overview | 339 |
| 7.1.1 | Features of PBIST | 339 |
| 7.1.2 | PBIST vs. Application Software-Based Testing..... | 339 |
| 7.1.3 | PBIST Block Diagram | 339 |
| 7.2 | RAM Grouping and Algorithm | 340 |
| 7.3 | PBIST Flow | 341 |
| 7.3.1 | PBIST Sequence | 342 |
| 7.4 | Memory Test Algorithms on the On-chip ROM | 343 |
| 7.5 | PBIST Control Registers | 345 |
| 7.5.1 | RAM Configuration Register (RAMT) | 346 |
| 7.5.2 | Datalogger Register (DLR) | 347 |

| | | |
|-----------|--|------------|
| 7.5.3 | PBIST Activate/ROM Clock Enable Register (PACT) | 348 |
| 7.5.4 | PBIST ID Register | 349 |
| 7.5.5 | Override Register (OVER) | 350 |
| 7.5.6 | Fail Status Fail Register (FSRF0) | 351 |
| 7.5.7 | Fail Status Count Registers (FSRC0 and FSRC1) | 352 |
| 7.5.8 | Fail Status Address Registers (FSRA0 and FSRA1) | 353 |
| 7.5.9 | Fail Status Data Registers (FSRDL0 and FSRDL1) | 354 |
| 7.5.10 | ROM Mask Register (ROM) | 355 |
| 7.5.11 | ROM Algorithm Mask Register (ALGO) | 355 |
| 7.5.12 | RAM Info Mask Lower Register (RINFOL) | 356 |
| 7.5.13 | RAM Info Mask Upper Register (RINFOU) | 357 |
| 7.6 | PBIST Configuration Example | 358 |
| 7.6.1 | Example 1 : Configuration of PBIST Controller to Run Self-Test on RAM Group 3 | 358 |
| 7.6.2 | Example 2 : Configuration of PBIST Controller to Run Self-Test on ALL RAM Groups | 359 |
| 8 | CPU Self-Test Controller (STC) Module | 360 |
| 8.1 | General Description | 361 |
| 8.1.1 | CPU Self-Test Controller Features | 361 |
| 8.1.2 | STC Block Diagram | 361 |
| 8.2 | Application Self-Test Flow | 363 |
| 8.2.1 | STC Module Configuration | 363 |
| 8.2.2 | Context Saving | 363 |
| 8.2.3 | Entering CPU Idle Mode | 363 |
| 8.2.4 | Self-Test Completion and Error Generation | 364 |
| 8.3 | STC Test Coverage and Duration | 365 |
| 8.4 | STC Control Registers | 366 |
| 8.4.1 | STC Global Control Register 0 (STCGCR0) | 367 |
| 8.4.2 | STC Global Control Register 1 (STCGCR1) | 367 |
| 8.4.3 | Self-Test Run Timeout Counter Preload Register (STCTPR) | 368 |
| 8.4.4 | STC Current ROM Address Register (STC_CADDR) | 368 |
| 8.4.5 | STC Current Interval Count Register (STCCICR) | 369 |
| 8.4.6 | Self-Test Global Status Register (STCGSTAT) | 370 |
| 8.4.7 | Self-Test Fail Status Register (STCFSTAT) | 371 |
| 8.4.8 | CPU1 Current MISR Register (CPU1_CURMISR[3:0]) | 372 |
| 8.4.9 | CPU2_CURMISR[3:0] (CPU2 Current MISR Register) | 373 |
| 8.4.10 | STCSCSCR (Signature Compare Self-Check Register) | 374 |
| 8.5 | STC Configuration Example | 375 |
| 8.5.1 | Example 1: Self-Test Run for 24 Interval | 375 |
| 9 | CPU Compare Module for Cortex-R4F (CCM-R4F) | 376 |
| 9.1 | Main Features | 377 |
| 9.2 | Block Diagram | 377 |
| 9.3 | Module Operation | 378 |
| 9.3.1 | 1001D Lock Step Mode | 378 |
| 9.3.2 | Self-Test Mode | 378 |
| 9.3.3 | Error Forcing Mode | 380 |
| 9.3.4 | Self-Test Error Forcing Mode | 380 |
| 9.3.5 | Operation During CPU Debug Mode | 381 |
| 9.4 | CCM-R4F Control Registers | 381 |
| 9.4.1 | CCM-R4F Status Register (CCMSR) | 382 |
| 9.4.2 | CCM-R4F Key Register (CCMKEYR) | 383 |
| 10 | Oscillator and PLL | 384 |
| 10.1 | Introduction | 385 |
| 10.1.1 | Features | 385 |
| 10.2 | Quick Start | 386 |

| | | |
|-----------|--|------------|
| 10.3 | Oscillator | 387 |
| 10.3.1 | Oscillator Implementation..... | 388 |
| 10.3.2 | Oscillator Enable..... | 388 |
| 10.3.3 | Oscillator Disable | 388 |
| 10.4 | Low-Power Oscillator and Clock Detect (LPOCLKDET)..... | 389 |
| 10.4.1 | Clock Detect..... | 389 |
| 10.4.2 | Behavior on Oscillator Failure..... | 389 |
| 10.4.3 | Recovery from Oscillator Failure | 390 |
| 10.4.4 | LPOCLKDET Enable | 390 |
| 10.4.5 | LPOCLKDET Disable | 391 |
| 10.4.6 | Trimming the HF LPO Oscillator..... | 391 |
| 10.5 | PLL | 392 |
| 10.5.1 | Modulation | 394 |
| 10.5.2 | PLL Output Control | 395 |
| 10.5.3 | Behavior on PLL Fail | 398 |
| 10.5.4 | Recovery from a PLL Failure..... | 399 |
| 10.5.5 | PLL Modulation Depth Measurement | 399 |
| 10.5.6 | PLL Frequency Measurement Circuit | 400 |
| 10.5.7 | PLL2..... | 400 |
| 10.6 | PLL Control Registers..... | 401 |
| 10.6.1 | PLL Modulation Depth Measurement Control Register (SSWPLL1)..... | 402 |
| 10.6.2 | SSW PLL BIST Control Register 2 (SSWPLL2) | 403 |
| 10.6.3 | SSW PLL BIST Control Register 3 (SSWPLL3) | 404 |
| 10.7 | Phase-Locked Loop Theory of Operation | 405 |
| 10.7.1 | Phase-Frequency Detector | 405 |
| 10.7.2 | Charge Pump and Loop Filter..... | 406 |
| 10.7.3 | Voltage-Controlled Oscillator..... | 406 |
| 10.7.4 | Frequency Modulation | 407 |
| 10.8 | Programming Example..... | 407 |
| 11 | Dual-Clock Comparator (DCC) Module | 409 |
| 11.1 | Introduction | 410 |
| 11.1.1 | Main Features | 410 |
| 11.1.2 | Block Diagram..... | 410 |
| 11.2 | Module Operation..... | 411 |
| 11.2.1 | Continuous Monitoring Mode..... | 411 |
| 11.2.2 | Single-Shot Measurement Mode | 414 |
| 11.3 | Clock Source Selection for Counter0 and Counter1 | 415 |
| 11.4 | DCC Control Registers..... | 416 |
| 11.4.1 | DCC Global Control Register (DCCGCTRL) | 417 |
| 11.4.2 | DCC Revision Id Register (DCCREV) | 418 |
| 11.4.3 | DCC Counter0 Seed Register (DCCCNT0SEED) | 418 |
| 11.4.4 | DCC Valid0 Seed Register (DCCVALID0SEED) | 419 |
| 11.4.5 | DCC Counter1 Seed Register (DCCCNT1SEED) | 419 |
| 11.4.6 | DCC Status Register (DCCSTAT) | 420 |
| 11.4.7 | DCC Counter0 Value Register (DCCCNT0) | 421 |
| 11.4.8 | DCC Valid0 Value Register (DCCVALID0) | 422 |
| 11.4.9 | DCC Counter1 Value Register (DCCCNT1) | 422 |
| 11.4.10 | DCC Counter1 Clock Source Selection Register (DCCCNT1CLKSRC) | 423 |
| 11.4.11 | DCC Counter0 Clock Source Selection Register (DCCCNT0CLKSRC) | 423 |
| 12 | Error Signaling Module (ESM) | 424 |
| 12.1 | Overview | 425 |
| 12.1.1 | Features..... | 425 |
| 12.1.2 | Block Diagram | 425 |

| | | |
|-----------|--|------------|
| 12.2 | Module Operation | 427 |
| 12.2.1 | Reset Behavior | 427 |
| 12.2.2 | ERROR Pin Timing | 428 |
| 12.2.3 | Forcing an Error Condition | 430 |
| 12.3 | Recommended Programming Procedure | 431 |
| 12.4 | Control Registers | 432 |
| 12.4.1 | ESM Enable ERROR Pin Action/Response Register 1 (ESMEEPAPR1)..... | 433 |
| 12.4.2 | ESM Disable ERROR Pin Action/Response Register 1 (ESMDEPAPR1)..... | 433 |
| 12.4.3 | ESM Interrupt Enable Set Register 1 (ESMIESR1) | 434 |
| 12.4.4 | ESM Interrupt Enable Clear Register 1 (ESMIECR1) | 434 |
| 12.4.5 | ESM Interrupt Level Set Register 1 (ESMILSR1) | 435 |
| 12.4.6 | ESM Interrupt Level Clear Register 1 (ESMILCR1)..... | 435 |
| 12.4.7 | ESM Status Register 1 (ESMSR1) | 436 |
| 12.4.8 | ESM Status Register 2 (ESMSR2) | 436 |
| 12.4.9 | ESM Status Register 3 (ESMSR3) | 437 |
| 12.4.10 | ESM ERROR Pin Status Register (ESMEPSR) | 437 |
| 12.4.11 | ESM Interrupt Offset High Register (ESMIOFFHR) | 438 |
| 12.4.12 | ESM Interrupt Offset Low Register (ESMIOFFLR) | 439 |

About This Manual

This Technical Reference Manual (TRM) details the integration, the environment, the functional description, and the programming models for each peripheral and subsystem in the device.

The TRM should not be considered a substitute for the data manual, rather a companion guide that should be used alongside the device-specific data manual to understand the details to program the device. The primary purpose of the TRM is to abstract the programming details of the device from the data manual. This allows the data manual to outline the high-level features of the device without unnecessary information about register descriptions or programming models.

Notational Conventions

This document uses the following conventions.

- Hexadecimal numbers may be shown with the suffix h or the prefix 0x. For example, the following number is 40 hexadecimal (decimal 64): 40h or 0x40
- Registers in this document are shown in figures and described in tables.
 - Each register figure shows a rectangle divided into fields that represent the fields of the register. Each field is labeled with its bit name, its beginning and ending bit numbers above, and its read/write properties with default reset value below. A legend explains the notation used for the properties.
 - Reserved bits in a register figure can have one of multiple meanings:
 - Not implemented on the device
 - Reserved for future device expansion
 - Reserved for TI testing
 - Reserved configurations of the device that are not supported
 - Writing non-default values to the Reserved bits could cause unexpected behavior and should be avoided.

1.1 Designed for Safety Applications

The TMS570LS12x/11x device architecture has been designed from the ground up to simplify development of functionally safe systems. The basic architectural concept is known as a safe island approach. Power, clock, reset, and basic processing function are protected to a high level of diagnostic coverage in hardware. Some of the key features of the safe island region are:

- A dual core lockstep processing solution built around ARM® Cortex®-R4F CPU that detects failures at the core boundary on a cycle by cycle basis. Special measures in processor layout, clock distribution, power distribution, reset distribution, and temporal diversity are all implemented to mitigate common cause failures of the logical CPU and its checker. For complete details on the ARM® Cortex®-R4F CPU, refer to the [ARM® Cortex®-R4F Technical Reference Manual](#).
- Hardware BIST controllers which provide an extremely high level of diagnostic coverage for the lockstep CPUs and SRAMs in the system, while executing faster and consuming less memory than equivalent software-based self-test solutions
- ECC on the SRAM and flash memories tightly coupled to the R4F. The ECC controllers are located inside the CPU. This approach has two key advantages:
 - The interconnect between CPU and the memory is also covered by the diagnostic
 - The ECC logic itself is checked on a cycle by cycle basis
- Onboard voltage and reset monitoring logic
- Onboard oscillator and PLL failure detection logic including a backup RC oscillator which can be utilized upon failure

The TMS570LS12x/11x device architecture also includes many features to simplify diagnostics of remaining logic such as:

- Continuous parity diagnostics on all peripheral memories
- Analog and digital loopback to test for shorts on I/O
- HW self-test and diagnostics on the ADC module to check integrity of both analog inputs and the ADC core conversion function
- A DMA driven hardware engine for the background calculation of CRC signatures during data transfers
- A centralized error reporting function including a status output pin to enable external monitoring of the device status

1.2 Family Description

The TMS570LS12x/11x integrates the ARM® Cortex®-R4F Floating Point CPU that offers an efficient 1.6 DMIPS/MHz and has configurations that can run up to 180MHz providing up to 288 DMIPS. The device supports the big-endian [BE32] format.

The TMS570LS12x/11x has up to 1.25MB integrated Flash and up to 192KB data RAM configurations with single bit error correction and double bit error detection. The flash memory on this device is a nonvolatile, electrically erasable and programmable memory implemented with a 64-bit-wide data bus interface. The flash operates on a 3.3V supply input (same level as I/O supply) for all read, program and erase operations. When in pipeline mode, the flash operates with a system clock frequency of up to 180MHz. The SRAM supports single-cycle read/write accesses in byte, halfword, and word modes.

The TMS570LS12x/11x device features peripherals for real-time control-based applications, including two Next Generation High End Timer (N2HET) timing coprocessors with up to 40 total IO terminals and a 12-bit A to D converter supporting up to 24 inputs.

The N2HET is an advanced intelligent timer that provides sophisticated timing functions for real-time applications. The timer is software-controlled, using a reduced instruction set, with a specialized timer micromachine and an attached I/O port. The N2HET can be used for pulse width modulated outputs, capture or compare inputs, or general-purpose I/O. It is especially well suited for applications requiring multiple sensor information and drive actuators with complex and accurate time pulses. A High End Timer Transfer Unit (HET-TU) can perform DMA type transactions to transfer N2HET data to or from main memory. A Memory Protection Unit (MPU) is built into the HET-TU.

The device has two 12-bit-resolution MibADCs with 24 total channels and 64 words of parity protected buffer RAM each. The MibADC channels can be converted individually or can be grouped by software for sequential conversion sequences. Sixteen channels are shared between the two MibADCs. There are three separate groupings. Each sequence can be converted once when triggered or configured for continuous conversion mode.

The device has multiple communication interfaces: three MibSPIs, up to two SPIs, one LIN, one SCI, three DCANs, one I²C, one Ethernet, and one FlexRay controller. The SPI provides a convenient method of serial interaction for high-speed communications between similar shift-register type devices. The LIN supports the Local Interconnect standard 2.0 and can be used as a UART in full-duplex mode using the standard Non-Return-to-Zero (NRZ) format. The DCAN supports the CAN 2.0B protocol standard and uses a serial, multimaster communication protocol that efficiently supports distributed real-time control with robust communication rates of up to 1 megabit per second (Mbps). The DCAN is ideal for applications operating in noisy and harsh environments (for example, automotive and industrial fields) that require reliable serial communication or multiplexed wiring. The FlexRay uses a dual channel serial, fixed time base multimaster communication protocol with communication rates of 10 megabits per second (Mbps) per channel. A FlexRay Transfer Unit (FTU) enables autonomous transfers of FlexRay data to and from main CPU memory. Transfers are protected by a dedicated, built-in Memory Protection Unit (MPU). The Ethernet module supports MII and MDIO interfaces.

The I2C module is a multi-master communication module providing an interface between the microcontroller and an I2C compatible device via the I2C serial bus. The I2C supports both 100 Kbps and 400 Kbps speeds.

The frequency-modulated phase-locked loop (FMPLL) clock module is used to multiply the external frequency reference to a higher frequency for internal use. The FMPLL provides one of the seven possible clock source inputs to the global clock module (GCM). The GCM module manages the mapping between the available clock sources and the device clock domains.

The device also has an external clock prescaler (ECP) module that when enabled, outputs a continuous external clock on the ECLK pin/ball. The ECLK frequency is a user-programmable ratio of the peripheral interface clock (VCLK) frequency. This low frequency output can be monitored externally as an indicator of the device operating frequency.

The Direct Memory Access Controller (DMA) has 16 channels, 32 control packets and parity protection on its memory. A Memory Protection Unit (MPU) is built into the DMA to protect memory against erroneous transfers.

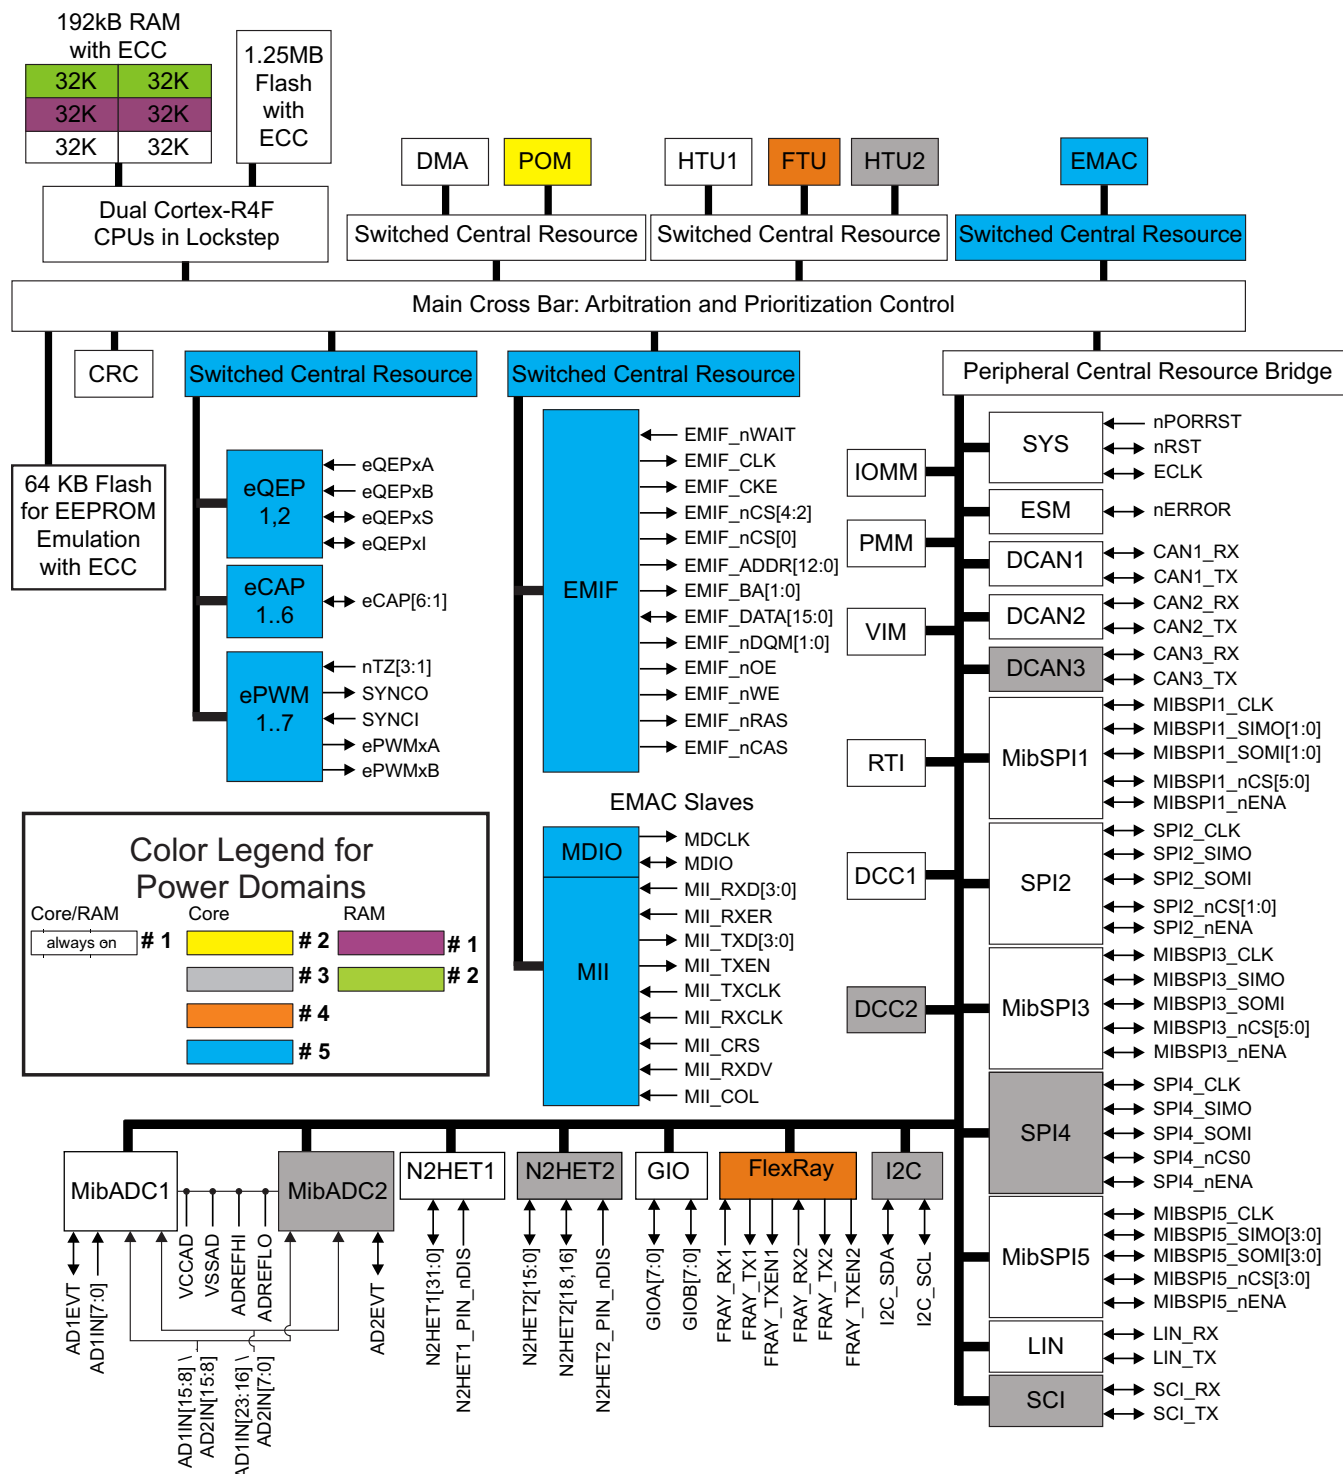

The Error Signaling Module (ESM) monitors all device errors and determines whether an interrupt or external Error pin/ball is triggered when a fault is detected. The nERROR can be monitored externally as an indicator of a fault condition in the microcontroller.

The External Memory Interface (EMIF) provides a memory extension to asynchronous and synchronous memories or other slave devices.

The device supports all the built-in ARM® Cortex®-R4F CoreSight™ debug features. In addition, a Parameter Overlay Module (POM) can re-route Flash accesses to internal memory or to external memory via the EMIF, thus avoiding the re-programming steps necessary for parameter updates in Flash.

With integrated safety features and a wide choice of communication and control peripherals, the TMS570LS12x/11x is an ideal solution for high performance real time control applications with safety critical requirements.

Figure 1-1. Block Diagram

1.3 Endianism Considerations

1.3.1 TMS570: Big Endian (BE32)

The TMS570 family is based on the ARM® Cortex®-R4F core. ARM has designed this core to be used in big-endian and little-endian systems. For the TI TMS570 family, the endianness has been configured to BE32. Big-endian systems store the most-significant byte of a multi-byte data field in the lowest memory address. Also, the address of the multi-byte data field is the lowest address. Following is an example of the physical addresses of individual bytes.

Figure 1-2. Example: SPIDELAY – 0xFFFF7F448

| | | | |
|----------------------|----|----------------------|----|
| 31 | 24 | 23 | 16 |
| C2TDELAY[7:0] | | T2CDELAY[7:0] | |
| Byte 3 - 0xFFFF7F448 | | Byte 2 - 0xFFFF7F449 | |
| 15 | 8 | 7 | 0 |
| T2EDELAY[7:0] | | C2EDELAY[7:0] | |
| Byte 1 - 0xFFFF7F44A | | Byte 0 - 0xFFFF7F44B | |

32-bit accesses to this register should use the lowest address, that is, 0xFFFF7F448. Writing 0x11223344 to address 0xFFFF7F448 shows the following when viewing the memory in 8-bit and 32-bit modes.

As such the headers provided as part of HALCoGen do take the endianness into account and provide header structures that are agnostic to endianness. This is achieved by using C directives for the compiler that make use of the compile options configured for the project by the user (`__little_endian__` used in Code Composer Studio codegen tools). This directive may need to be adapted for other compilers.

```
#ifdef __little_endian__
    char C2DELAY      : 8U; /**lt; 0xF448: CS to ENA      */
    char T2DELAY      : 8U; /**lt; 0xF449: Transmit to ENA */
    char T2CDELAY     : 8U; /**lt; 0xF44A: Transmit to CS  */
    char C2TDELAY     : 8U; /**lt; 0xF44B: CS to Transmit */
#else
    char C2DELAY      : 8U; /**lt; 0xF448: CS to Transmit */
    char T2CDELAY     : 8U; /**lt; 0xF449: Transmit to CS  */
    char T2DELAY      : 8U; /**lt; 0xF44A: Transmit to ENA */
    char C2EDELAY     : 8U; /**lt; 0xF44B: CS to ENA      */
#endif
```

Architecture

This chapter consists of five sections. The first section describes specific aspects of the device architecture. The second section describes the clocking structure of the microcontrollers. The third section gives an overview of the device memory organization. The fourth section details exceptions on the device, and the last section describes the system and peripheral control registers of the microcontroller.

2.1 Introduction

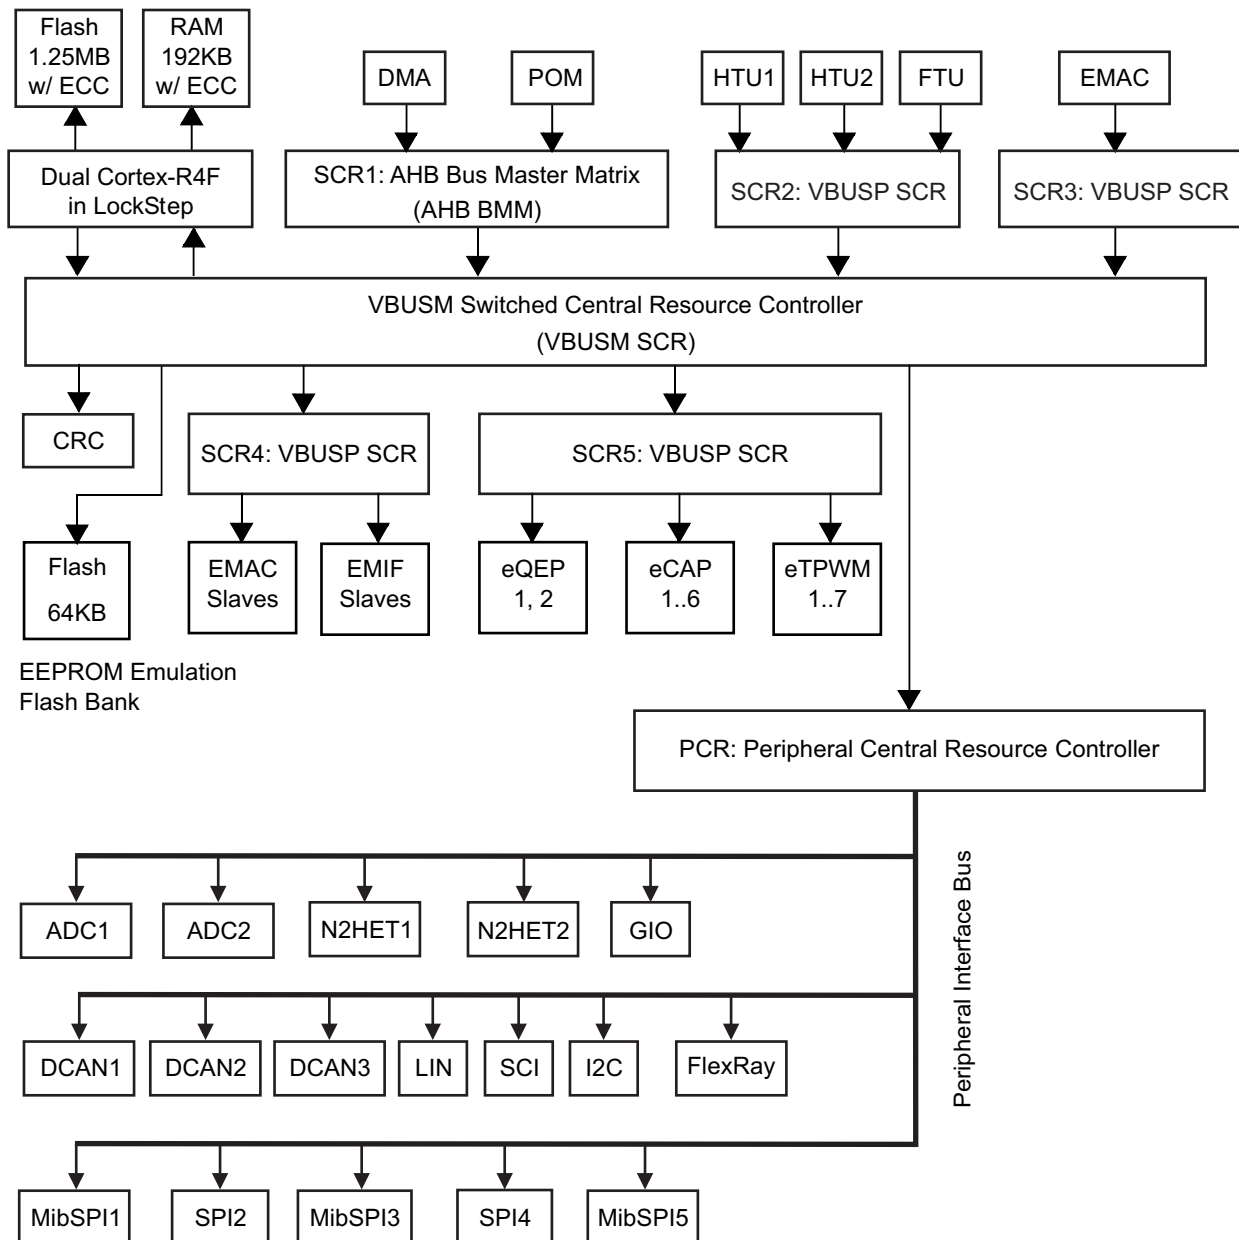

The TMS570LS12x/11x family of microcontrollers is based on the Texas Instruments TMS570 Architecture. This chapter describes specific aspects of the architecture as applicable to the TMS570LS12x/11x family of microcontrollers.

2.1.1 Architecture Block Diagram

The TMS570LS12x/11x microcontrollers are based on the TMS570 Platform architecture, which defines the interconnect between the bus masters and the bus slaves.

Figure 2-1 shows a high-level architectural block diagram for the superset microcontroller.

Figure 2-1. Architectural Block Diagram

2.1.2 Definitions of Terms

Table 2-1 provides a definition of terms used in the architectural block diagram.

Table 2-1. Definition of Terms

| Acronym / Term | Full Form | Description |
|----------------|--|---|
| ADCx | Analog-to-Digital Converter | The ADC uses the Successive Approximation Register architecture. It features a selectable 10-bit or 12-bit resolution. The ADC module also includes a RAM to hold the conversion results. A digital logic wrapper manages accesses to the control and status registers. There are two ADC modules on this device. |
| CRC | Cyclic Redundancy Checker | The CRC module provides two channels to perform background signature verification on any memory region. It also supports maximum-length Parallel Signature Analysis (PSA) based on a 64-bit primitive polynomial. The CRC module is a bus slave in this device. |
| DAP | Debug Access Port | The DAP allows a tool such as a debugger to read from or write to any region in the device memory-map. The DAP is a bus master in this device. |
| DCANx | Controller Area Network controller | The DCAN supports the CAN 2.0B protocol standard and uses a serial, multi-master communication protocol that efficiently supports distributed real-time control with robust communication rates of up to 1 megabit per second (Mbps). The DCAN is ideal for applications operating in noisy and harsh environments (for example, automotive and industrial fields) that require reliable serial communication or multiplexed wiring. |
| DMA | Direct Memory Access | The DMA module is used for transferring 8-, 16-, 32- or 64-bit data across the entire device memory-map. The DMA module is one of the bus masters on the device. That is, it can initiate a read or a write transaction. |
| eCAP | Enhanced Capture Module | The enhanced Capture (eCAP) module is essential in systems where accurate timing of external events is important. |
| eFuse | Electronically Programmable Fuse controller | Electrically programmable fuses (eFuses) are used to configure the device after deassertion of PORST. The eFuse values are read and loaded into internal registers as part of the power-on-reset sequence. The eFuse values are protected with single bit error correction, double bit error detection (SECDED) codes. These fuses are programmed during the initial factory test of the device. The eFuse controller is designed so that the state of the eFuses cannot be changed once the device is packaged. |
| ePWM | Enhanced Pulse Width Modulator | The enhanced pulse width modulator (ePWM) peripheral is a key element in controlling many of the power electronic systems found in both commercial and industrial equipments. These systems include digital motor control, switch mode power supply control, uninterruptible power supplies (UPS), and other forms of power conversion. The ePWM peripheral performs a digital to analog (DAC) function, where the duty cycle is equivalent to a DAC analog value; it is sometimes referred to as a Power DAC. |
| eQEP | Enhanced Quadrature Encoder Pulse Module | The enhanced quadrature encoder pulse (eQEP) module is used for direct interface with a linear or rotary incremental encoder to get position, direction, and speed information from a rotating machine for use in a high-performance motion and position-control system. |
| ECC | Error Correction Code | This is a code that is used by the Single Error Correction Double Error Detection (SECDED) logic inside the two Cortex-R4F processors (CPUs). There are 8 bits of ECC for every 64 bits of data accessed from the CPU tightly-coupled memories (flash and RAM). |
| EMAC | Ethernet Media Access Controller | The EMAC has a dedicated DMA-type component that is used to transfer data to / from the EMAC descriptor memory from / to another memory in the device memory-map. This DMA-type component of the EMAC is a bus master in this device. |
| EMAC slaves | Ethernet Media Access Controller slave ports | There are four EMAC slaves: <ol style="list-style-type: none"> 1. EMAC Control Module: this provides an interface between the EMAC and MDIO modules and the bus masters. It also includes 8KB of RAM to hold EMAC packet buffer descriptors. 2. EMAC: The EMAC module interfaces to the other devices on the Ethernet Network using the Media Independent Interface (MII) or Reduced Media Independent Interface (RMII). 3. Management Data Input / Output (MDIO): The MDIO module is used to manage the physical layer (PHY) device connected to the EMAC module. 4. Communications Port Programming Interface (CPPI): This is the 8KB of RAM used to hold the EMAC packet buffer descriptors. |

Table 2-1. Definition of Terms (continued)

| Acronym / Term | Full Form | Description |
|-----------------------------|--|---|
| EEPROM Emulation Flash Bank | Emulated Electrically Erasable Programmable Read-Only Memory | This is a flash bank that is dedicated for use as an emulated EEPROM. This device supports 64KB of flash for emulated EEPROM. |
| EMIF slaves | External Memory Interface slave ports | There are five EMIF slaves:- External SDRAM memory: EMIF chip select 0- External asynchronous memories: EMIF chip selects 2, 3 and 4- EMIF module control and status registers |
| FlexRay | FlexRay communication controller | The FlexRay uses a dual channel serial, fixed time base multi-master communication protocol with communication rates of 10 megabits per second (Mbps) per channel. |
| FTU | FlexRay Transfer Unit | The FTU is a dedicated transfer unit for the FlexRay communication interface controller. The FTU has a native interface to the FlexRay message RAM and is used to transfer data to / from the FlexRay message RAM from / to another region in the device memory-map. The FTU is a bus master in this device. |
| GIO | General-purpose Input/Output | The GIO module allows up to 16 terminals to be used as general-purpose Input or Output. Each of these are also capable of generating an interrupt to the CPU. |
| HTUx | High-end timer Transfer Unit | The HTU is a dedicated transfer unit for the New Enhanced High-End Timer module. The HTU has a native interface to the N2HET RAM, and is used to transfer data to and from the N2HET RAM from and to another region in the device memory-map. There is one HTU per N2HET module, so that there are 2 HTU modules on the device. The HTUx are bus masters in this device. |
| I2C | Inter-Integrated Circuit controller | The I2C module is a multi-master communication module providing an interface between the device and an I2C-compatible device via the I2C serial bus. The I2C supports both 100 Kbps and 400 Kbps speeds. |
| LIN | Local Interconnect Network controller | The LIN module supports the Local Interconnect standard revision 2.1 and can be used as a UART in full-duplex mode using the standard Non-Return-to-Zero (NRZ) format. |
| Lockstep | – | This is the mode of operation of the dual ARM Cortex-R4F CPUs. The outputs of the two CPUs are compared on each CPU clock cycle. Any miscompare is flagged as an error of the highest severity level. |
| MibSPIx | Multi-Buffered Serial Peripheral Interface | The MibSPIx modules also support the standard SPI communication protocol. The transfers are all grouped into transfer chunks called “transfer groups”. These transfer groups are made up of one or more buffers in the MibSPIx RAM. The RAM is used to hold the control information and data to be transmitted, as well as the status information and data that is received. There are three MibSPI modules in this device. |
| N2HETx | New Enhanced High-End Timer | The N2HET is an advanced intelligent timer that provides sophisticated timing functions for real-time applications. The timer is software-controlled, using a reduced instruction set, with a specialized timer micromachine and an attached I/O port. The N2HET can be used for pulse width modulated outputs, capture or compare inputs, or general-purpose I/O. |
| PCR | Peripheral Central Resource controller | The PCR manages the accesses to the peripheral registers and peripheral memories. It provides a global reset for all the peripherals. It also supports the capability to selectively enable or disable the clock for each peripheral individually. The PCR also manages the accesses to the system module registers required to configure the device's clocks, interrupts, and so on. The system module registers also include status flags for indicating exception conditions – resets, aborts, errors, interrupts. |
| POM | Parameter Overlay Module | The parameter overlay module redirects accesses to a programmable region in flash memory (read-only) to a RAM memory, either on-chip or via the external memory interface (EMIF). This allows a user to evaluate the impact of changing values of constants stored in the flash memory without actually having to erase and reprogram the flash. The POM is also a bus master in this device. |
| SCI | Serial Communication Interface | The SCI module supports the standard UART in full-duplex mode using the standard Non-Return-to-Zero (NRZ) format. |
| SCR1: AHB BMM | AMBA High-performance Bus Matrix Module | The DMA, POM and DAP all act as masters on the AMBA High-performance Bus (AHB). The BMM arbitrates between concurrent accesses by these masters using a fixed priority scheme. The modules in descending order of priority are POM → DMA → DAP. |
| SCR2: VBUSP SCR | VBUSP Switched Central Resource Controller | The SCR2 arbitrates between concurrent accesses by the HTUx and FTU modules. A round-robin priority scheme is used between the HTUx and FTU. |

Table 2-1. Definition of Terms (continued)

| Acronym / Term | Full Form | Description |
|--------------------|--|---|
| SCR3: VBUSP SCR | VBUSP Switched Central Resource Controller | The SCR3 arbitrates between concurrent accesses by the EMAC and another module that is not available in this configuration of the device. |
| SCR4: VBUSP SCR | VBUSP Switched Central Resource Controller | The SCR4 is used to decode the accesses to the bus slaves for the EMAC and EMIF modules. SCR4 is a bus slave in this device. |
| SPIx | Serial Peripheral Interface | The SPIx module provides a clocked serial communication interface for reliable communication between the device and other serial devices with the standard SPI interface. There are two SPI modules on this device. |
| VBUSM SCR | VBUSM Switched Central Resource Controller | This is the main device SCR. It arbitrates between the accesses from multiple bus masters to the bus slaves using a round robin priority scheme. |

2.1.3 Bus Master / Slave Access Privileges

This device implements some restrictions on the bus slave access privileges, see [Table 2-2](#), in order to improve the overall throughput of the interconnect shown in [Figure 2-1](#).

Table 2-2. Bus Master / Slave Access Privileges

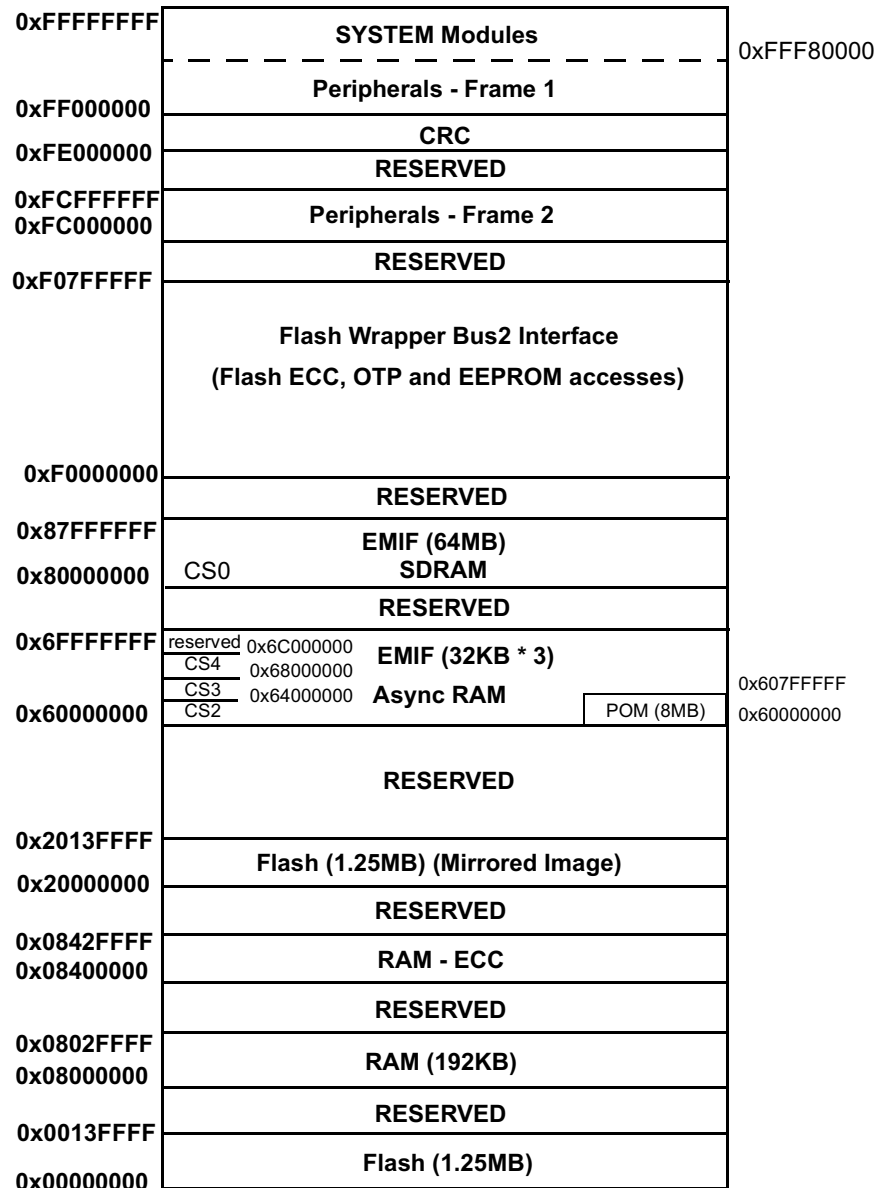

| Bus Masters | Master Id | Bus Slaves Being Accessed | | | | |
|-------------|-----------|------------------------------------|---------------------------------------|-------------|----------------------|-------------|
| | | EEPROM Bank, ECC Bits, OTP Regions | Non-CPU Accesses to CPU Flash and RAM | CRC Module | EMAC and EMIF Slaves | PCR Modules |
| CPU Read | 0 | Allowed | Allowed | Allowed | Allowed | Allowed |
| CPU Write | 1 | Not allowed | Allowed | Allowed | Allowed | Allowed |
| POM | 2 | Allowed | Allowed | Allowed | Allowed | Allowed |
| DMA | 3 | Allowed | Allowed | Allowed | Allowed | Allowed |
| DAP | 5 | Allowed | Allowed | Allowed | Allowed | Allowed |
| HTU1 | 6 | Not allowed | Allowed | Allowed | Allowed | Allowed |
| FTU | 7 | Not allowed | Allowed | Allowed | Allowed | Allowed |
| HTU2 | 8 | Not allowed | Allowed | Allowed | Allowed | Allowed |
| EMAC | 9 | Not allowed | Allowed | Not allowed | Allowed | Not allowed |

2.2 Memory Organization

2.2.1 Memory-Map Overview

The Cortex-R4F uses a 32-bit address bus, giving it access to a memory space of 4GB. This space is divided into several regions, each addressed by different memory selects. Figure 2-2 shows the memory-map of the microcontroller.

Figure 2-2. Memory-Map

The main flash instruction memory is addressed starting at 0x00000000 by default. This is also the reset vector location – the ARM Cortex-R4F processor core starts execution from the reset vector address of 0x00000000 whenever the core gets reset.

The CPU data RAM is addressed starting at 0x08000000 by default.

The device also supports the swapping of the CPU instruction memory (flash) and data memory (RAM). This can be done by configuring the MEM SWAP field of the Bus Matrix Module Control Register 1 (BMMCR1).

After swapping, the data RAM is accessed starting from 0x00000000 and the RAM ECC locations are accessed starting from 0x00400000. The flash memory is now accessed starting from 0x08000000.

2.2.2 Memory-Map Table

The control and status registers for each module are mapped within the CPU's 4GB memory space. Some modules also have associated memories, which are also mapped within this space.

Table 2-3 shows the starting and ending addresses of each module's register frame and any associated memory. The table also shows the response generated by the module or the interconnect whenever an access is made to an unimplemented location inside the register or memory frame.

Table 2-3. Module Registers / Memories Memory-Map

| Name | Memory Select | Frame Address | | Frame Size | Actual Size | Response for Access to Unimplemented Location in Frame |
|---|--------------------|---------------|-------------|------------|-------------|--|
| | | Start | End | | | |
| CPU Tightly-Coupled Memories | | | | | | |
| TCM Flash | CS0 | 0x0000_0000 | 0x00FF_FFFF | 16MB | 1.25MB | Abort |
| TCM RAM + RAM ECC | CSRAM0 | 0x0800_0000 | 0x0BFF_FFFF | 64MB | 192KB | |
| Mirrored Flash | Flash mirror frame | 0x2000_0000 | 0x20FF_FFFF | 16MB | 1.25MB | |
| External Memory Accesses | | | | | | |
| EMIF Chip Select 2 (asynchronous) | EMIF select 2 | 0x6000_0000 | 0x63FF_FFFF | 64MB | 16MB | Access to “Reserved” space will generate Abort |
| EMIF Chip Select 3 (asynchronous) | EMIF select 3 | 0x6400_0000 | 0x67FF_FFFF | 64MB | 16MB | |
| EMIF Chip Select 4 (asynchronous) | EMIF select 4 | 0x6800_0000 | 0x6BFF_FFFF | 64MB | 16MB | |
| EMIF Chip Select 0 (synchronous) | EMIF select 0 | 0x8000_0000 | 0x87FF_FFFF | 128MB | 128MB | |
| Flash Bus2 Interface: OTP, ECC, EEPROM Bank | | | | | | |
| Customer OTP, TCM Flash Bank | | 0xF000_0000 | 0xF000_1FFF | 8KB | 4KB | Abort |
| Customer OTP, EEPROM Bank | | 0xF000_E000 | 0xF000_FFFF | 8KB | 4KB | |
| Customer OTP–ECC, TCM Flash Bank | | 0xF004_0000 | 0xF004_03FF | 1KB | 512B | |
| Customer OTP–ECC, EEPROM Bank | | 0xF004_1C00 | 0xF004_1FFF | 1KB | 512KB | |
| TI OTP, TCM Flash Bank | | 0xF008_0000 | 0xF008_1FFF | 8KB | 4KB | |
| TI OTP, EEPROM Bank | | 0xF008_E000 | 0xF008_FFFF | 8KB | 4KB | |
| TI OTP–ECC, TCM Flash Bank | | 0xF00C_0000 | 0xF00C_03FF | 1KB | 512B | |
| TI OTP–ECC, EEPROM Bank | | 0xF00C_1C00 | 0xF00C_1FFF | 1KB | 512KB | |
| EEPROM Bank–ECC | | 0xF010_0000 | 0xF013_FFFF | 256KB | 8KB | |
| EEPROM Bank | | 0xF020_0000 | 0xF03F_FFFF | 2MB | 64KB | |
| Flash Data Space ECC | | 0xF040_0000 | 0xF04F_FFFF | 1MB | 160KB | |
| EMAC and EMIF Slaves | | | | | | |
| CPPI Memory Slave (Ethernet RAM) | | 0xFC52_0000 | 0xFC52_1FFF | 8KB | 8KB | Abort |
| CPGMAC Slave (Ethernet Slave) | | 0xFCF7_8000 | 0xFCF7_87FF | 2KB | 2KB | No error |
| CPGMACSS Wrapper (Ethernet Wrapper) | | 0xFCF7_8800 | 0xFCF7_88FF | 256B | 256B | No error |

Table 2-3. Module Registers / Memories Memory-Map (continued)

| Name | Memory Select | Frame Address | | Frame Size | Actual Size | Response for Access to Unimplemented Location in Frame |
|---|---------------|---------------|-------------|------------|-------------|---|
| | | Start | End | | | |
| Ethernet MDIO Interface | | 0xFCF7_8900 | 0xFCF7_89FF | 256B | 256B | No error |
| ePWM1 | | 0xFCF7_8C00 | 0xFCF7_8CFF | 256B | 256B | Abort |
| ePWM2 | | 0xFCF7_8D00 | 0xFCF7_8DFF | 256B | 256B | Abort |

2.2.3 Flash on Microcontrollers

The TMS570LS12x/11x microcontrollers support up to 1.25MB of flash for use as program memory. The microcontrollers also support a separate 64KB flash bank for use as emulated EEPROM.

2.2.3.1 Flash Bank Sectoring Configuration

The bank is divided into multiple sectors. A flash sector is the smallest region in the flash bank that must be erased. The sectoring configuration of each flash bank is shown in [Table 2-4](#).

Table 2-4. Flash Memory Banks and Sectors ⁽¹⁾

| Memory Arrays (or Banks) | Block Number | Sector Number | Segment | Low Address | High Address |
|--------------------------|--------------|---------------|------------|-------------|--------------|
| BANK0 (1.25MBytes) | 0 | 0 | 16K Bytes | 0x0000_0000 | 0x0000_3FFF |
| | | 1 | 16K Bytes | 0x0000_4000 | 0x0000_7FFF |
| | | 2 | 16K Bytes | 0x0000_8000 | 0x0000_BFFF |
| | | 3 | 16K Bytes | 0x0000_C000 | 0x0000_FFFF |
| | | 4 | 16K Bytes | 0x0001_0000 | 0x0001_3FFF |
| | | 5 | 16K Bytes | 0x0001_4000 | 0x0001_7FFF |
| | | 6 | 32K Bytes | 0x0001_8000 | 0x0001_FFFF |
| | 1 | 7 | 128K Bytes | 0x0002_0000 | 0x0003_FFFF |
| | | 8 | 128K Bytes | 0x0004_0000 | 0x0005_FFFF |
| | 2 | 9 | 128K Bytes | 0x0006_0000 | 0x0007_FFFF |
| | | 10 | 128K Bytes | 0x0008_0000 | 0x0009_FFFF |
| | 3 | 11 | 128K Bytes | 0x000A_0000 | 0x000B_FFFF |
| | | 12 | 128K Bytes | 0x000C_0000 | 0x000D_FFFF |
| | 4 | 13 | 128K Bytes | 0x000E_0000 | 0x000F_FFFF |
| | | 14 | 128K Bytes | 0x0010_0000 | 0x0011_FFFF |
| | | 15 | 128K Bytes | 0x0012_0000 | 0x0013_FFFF |

⁽¹⁾

- The Flash banks are 144-bit wide bank with ECC support.
- The flash bank7 can be programmed while executing code from flash bank0.
- Code execution is not allowed from flash bank7.

Table 2-4. Flash Memory Banks and Sectors ⁽¹⁾ (continued)

| Memory Arrays (or Banks) | Block Number | Sector Number | Segment | Low Address | High Address |
|--|-----------------|------------------|-----------|-------------|--------------|
| BANK7 (64KBytes) for EEPROM emulation | 0 | 0 | 16K Bytes | 0xF020_0000 | 0xF020_3FFF |
| | 1 | 1 | 16K Bytes | 0xF020_4000 | 0xF020_7FFF |
| | 2 | 2 | 16K Bytes | 0xF020_8000 | 0xF020_BFFF |
| | 3 | 3 | 16K Bytes | 0xF020_C000 | 0xF020_FFFF |

Refer to the device datasheet for electrical and timing specifications related to the flash module.

2.2.3.2 ECC Protection for Flash Accesses

The TMS570LS12x/11x microcontrollers protect all accesses to the on-chip flash memory by dedicated Single-Error-Correction-Double-Error-Detection (SECEDED) logic.

The access to the program memory – flash bank 0, is protected by SECEDED logic implemented inside the ARM Cortex-R4F CPU. Accesses to the EEPROM emulation flash bank (bank 7) are protected by dedicated SECEDED logic inside the digital interface to the flash banks.

Both the SECEDED logic implementations use Error Correction Codes (ECC) for correcting single-bit errors and for detecting double-bit errors in the values read from the flash arrays. There is an 8-bit ECC for every 64 bits of data. The ECC for the flash memory contents needs to be calculated by an external tool such as nowECC. The ECC can then be programmed into the flash array along with the actual application code.

The ECC for the flash array is stored in the flash itself, and is mapped to a region starting at 0xF0400000 for the main flash bank 0, and to a region starting at 0xF0100000 for the EEPROM emulation flash bank 7.

NOTE: ECC Protection Not Enabled By Default

The SECEDED logic inside the CPU is not enabled by default and must be enabled by the application.

Code Example for Enabling ECC Protection for Main Flash Accesses:

The following code example can be used to enable the ECC protection for accesses to the main flash array:

```
MRC p15, #0, r1, c1, c0, #1
ORR r1, r1, #0x02000000      ;Enable ECC checking for ATCM
DMB
MCR p15, #0, r1, c1, c0, #1
```

The ECC protection for accesses to the EEPROM emulation flash bank can be enabled by writing 0xA to the EDACEN field of the flash module's Error Correction Control Register 1 (FEDACCTRL1). See [Chapter 5](#) for more details.

When the CPU detects an ECC single-, or double-bit error on a read from the flash memory, it signals this on a dedicated “*Event*” bus. This event bus signaling is also not enabled by default and must be enabled by the application. The following code example can be used to enable the CPU event signaling:

```
MRC p15,#0,r1,c9,c12,#0      ;Enabling Event monitor states
ORR r1, r1, #0x00000010
MCR p15,#0,r1,c9,c12,#0      ;Set 4th bit ('X') of PMNC register
MRC p15,#0,r1,c9,c12,#0
```

The digital logic that interfaces the ARM Cortex-R4F CPU to the flash banks captures the ECC error events signaled by the CPU, and in turn generates error signals that are input to the central Error Signaling Module (ESM).

2.2.4 On-Chip SRAM

Several SRAM modules are implemented on the device to support the functionality of the modules included.

Reads from the CPU data RAM are protected by ECC calculated inside the CPU. Reads from all other memories are protected by configurable odd or even parity that is evaluated in parallel with the actual read.

The TMS570LS12x/11x microcontrollers are targeted towards safety-critical applications, and it is critical for any failures in the on-chip SRAM modules to be identified before these modules are used for safety-critical functions. These microcontrollers support a Programmable Built-In Self-Test (PBIST) mechanism that is used to test each on-chip SRAM module for faults. The PBIST is usually run on device start-up as it is a destructive test and all contents of the tested SRAM module are overwritten during the test.

The microcontrollers also support a hardware-based auto-initialization of on-chip SRAM modules. This process also takes into account the read protection scheme implemented for each SRAM module – ECC or parity.

TI recommends that the PBIST routines be executed on the SRAM modules prior to the auto-initialization. The following section describe these two processes.

2.2.4.1 PBIST RAM Grouping and Algorithm Mapping For On-Chip SRAM Modules

Table 2-5 shows the groupings of the various on-chip memories for PBIST. It also lists the memory types and their assigned RAM Group Select (RGS) and Return Data Select (RDS). See Chapter 7 for more details on the usage of the RGS and RDS information.

Table 2-5. PBIST Memory Grouping

| Memory | RAM Group # | Memory Type | RGS | RDS |
|-----------|-------------|-------------|-----|----------|
| PBIST_ROM | 1 | ROM | 1 | 0 |
| STC_ROM | 2 | ROM | 2 | 0 |
| DCAN1 | 3 | Dual-port | 3 | 0 .. 5 |
| DCAN2 | 4 | Dual-port | 4 | 0 .. 5 |
| DCAN3 | 5 | Dual-port | 5 | 0 .. 5 |
| ESRAM1 | 6 | Single-port | 6 | 0/1 .. 4 |
| MIBSPI1 | 7 | Dual-port | 7 | 0 .. 3 |
| MIBSPI3 | 8 | Dual-port | 7 | 4 .. 7 |
| MIBSPI5 | 9 | Dual-port | 7 | 8 .. 11 |
| VIM | 10 | Dual-port | 8 | 0 .. 1 |
| MIBADC1 | 11 | Dual-port | 9 | 0 |
| DMA | 12 | Dual-port | 10 | 0 .. 5 |
| N2HET1 | 13 | Dual-port | 11 | 0 .. 11 |
| HET TU1 | 14 | Dual-port | 12 | 0 .. 5 |
| FLEXRAY | 16 | Dual-port | 14 | 0 .. 13 |
| | 17 | Single-port | | |
| MIBADC2 | 18 | Dual-port | 15 | 0 |
| N2HET2 | 19 | Dual-port | 16 | 0 .. 11 |
| HET TU2 | 20 | Dual-port | 17 | 0 .. 5 |
| ESRAM5 | 21 | Single-port | 18 | 0/1 .. 4 |
| ESRAM6 | 22 | Single-port | 19 | 0/1 .. 4 |
| ETHERNET | 23 | Dual-port | 20 | 0 .. 6 |
| | 24 | Dual-port | | |
| | 25 | Single-port | | |

Table 2-6 maps the different algorithms supported in application mode for the RAM groups. The table also lists the background pattern options available for each algorithm.

Table 2-6. PBIST Algorithm Mapping

| No. | ALGO MASK Register Value | Algorithm | Memories Tested | Available Background Patterns | Valid RAM Groups | Valid RAMINFO Register Value |
|-----|--------------------------|-----------------------|-----------------|--|---|------------------------------|
| 1 | 0x00000001 | triple_read_slow_read | ROM | | 1,2 | 0x00000003 |
| 2 | 0x00000002 | triple_read_fast_read | ROM | | 1,2 | 0x00000003 |
| 3 | 0x00000004 | march13n | two_port | 0x00000000, 0x96699669, 0x0F0F0F0F, 0xAA55AA55, 0xC3C3C3C3 | 3,4,5,7,8,9,10,11,12,13,14, 15,16,18,19,20,23,24,26 | 0x02CEBFDC |
| 4 | 0x00000008 | march13n | single_port | 0x00000000, 0x96699669, 0x0F0F0F0F, 0xAA55AA55, 0xC3C3C3C3 | 6,17,21,22,25 | 0x05310020 |

| 32 | 0x80000000 | powerup_invpowerup | single_port | 0xAAAAAAAA | 52,53,54,56,57,58 | 0x03B80000 |

NOTE: Recommended Memory Test Algorithm

March13 is the most recommended algorithm for the memory self-test.

For HCLK = 180 MHz, VCLK = 90 MHz, PBIST ROM_CLK = 90 MHz, the March13 algorithm takes 14.02 ms to run on all on-chip SRAMs.

2.2.4.2 Auto-Initialization of On-Chip SRAM Modules

The device system provides the capability to perform a hardware initialization on most memories on the system bus and on the peripheral bus. The memory used for the FlexRay message objects is not directly CPU addressable, hence there is no memory auto-initialization support for this memory.

The intent of having the hardware initialization is to program the memory arrays with error detection capability to a known state based on their error detection scheme – odd/even parity or ECC. For example, the contents of the CPU data RAM after power-on reset is unknown. A hardware auto-initialization can be started so that there is no ECC error.

NOTE: Effect of ECC or Parity on Memory Auto-Initialization

The ECC or parity should be enabled on the RAMs before hardware auto-initialization starts if parity or ECC is being used.

Auto-Initialization Sequence:

1. Enable the global hardware memory initialization key by programming 0xA into MINITGCR[3:0], the Memory Initialization Key field (MINITGENA) of the Memory Hardware Initialization Global Control Register (MINITGCR) register.
2. Select the module on which the memory hardware initialization has to be performed by programming the appropriate value into the MSINENA(31–0) bits in the MSINENA register. See [Table 2-7](#).
3. If the global auto-initialization scheme is enabled, the corresponding module will initialize its memories based on its memory error checking scheme (even parity or odd parity or ECC).
4. When the memory initialization is complete, the module will signal “memory initialization done”, which sets the corresponding bit in the system module MIDONE field of the MINISTAT register to indicate the completion of its memory initialization.
5. When the memory hardware initialization completes for all modules, (indicated by each module’s MIDONE bit being set), the memory hardware initialization done bit (MINIDONE) is set in the MSTCGSTAT register.

Figure 2-3. Hardware Memory Initialization Protocol

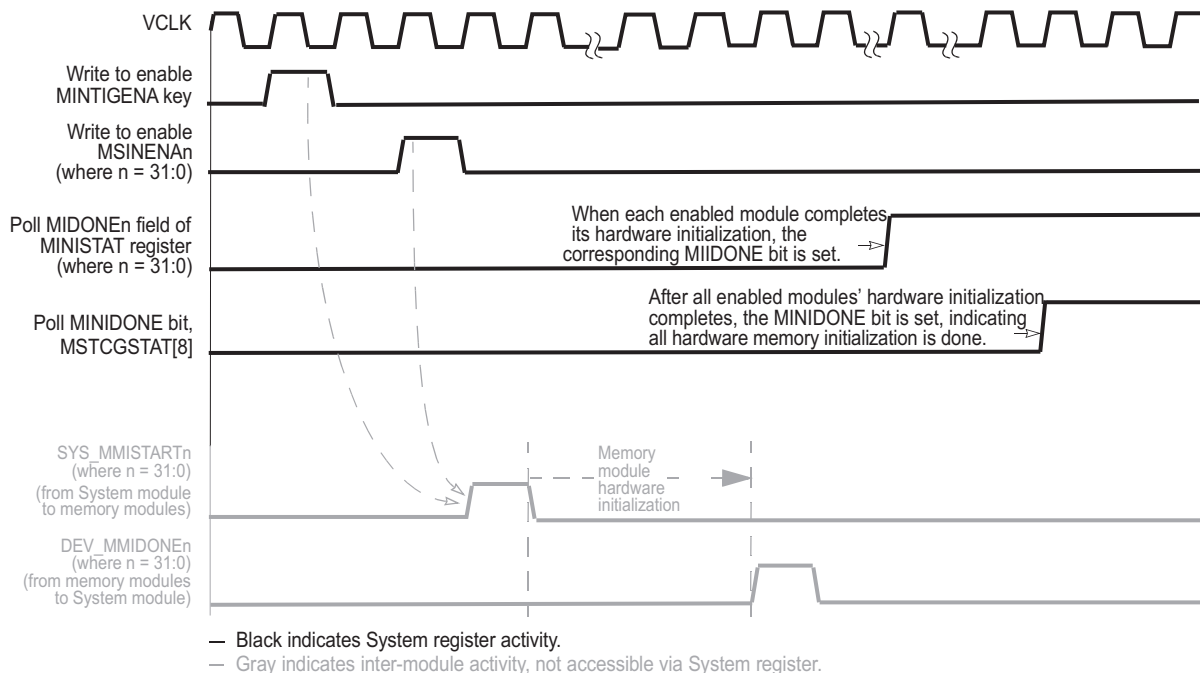

Table 2-7. Memory Initialization Select Mapping ⁽¹⁾⁽²⁾⁽³⁾

| Memory | Address Range | | MSINENA Register Bit # |
|----------------------------------|---------------|--------------|------------------------|
| | Start | End | |
| RAM (PD#1) | 0x08000000 | 0x08013FFF | 0 |
| RAM (RAM_PD#1) | 0x08010000 | 0x0801FFFF | 0 |
| RAM (RAM_PD#2) | 0x08020000 | 0x0802FFFF | 0 |
| MIBSPI5 RAM | 0xFF0A0000 | 0xFF0BFFFF | 12 ⁽⁴⁾ |
| MIBSPI3 RAM | 0xFF0C0000 | 0xFF0DFFFF | 11 ⁽⁴⁾ |
| MIBSPI1 RAM | 0xFF0E0000 | 0xFF0FFFFFFF | 7 ⁽⁴⁾ |
| DCAN3 RAM | 0xFF1A0000 | 0xFF1BFFFF | 10 |
| DCAN2 RAM | 0xFF1C0000 | 0xFF1DFFFF | 6 |
| DCAN1 RAM | 0xFF1E0000 | 0xFF1FFFFFFF | 5 |
| MIBADC2 RAM | 0xFF3A0000 | 0xFF3BFFFF | 14 |
| MIBADC1 RAM | 0xFF3E0000 | 0xFF3FFFFFFF | 8 |
| N2HET2 RAM | 0xFF440000 | 0xFF47FFFF | 15 |
| N2HET1 RAM | 0xFF460000 | 0xFF47FFFF | 3 |
| HET TU2 RAM | 0xFF4C0000 | 0xFF4DFFFF | 16 |
| HET TU1 RAM | 0xFF4E0000 | 0xFF4FFFFFFF | 4 |
| DMA RAM | 0xFFF80000 | 0xFFF80FFF | 1 |
| VIM RAM | 0xFFF82000 | 0xFFF82FFF | 2 |
| Ethernet RAM (CPPI Memory Slave) | 0xFC520000 | 0xFC521FFF | N/A |
| FlexRay TU RAM | 0xFF500000 | 0xFF51FFFF | 13 |

- ⁽¹⁾ If ECC protection is enabled for the CPU data RAM, then the auto-initialization process also initializes the corresponding ECC space.
- ⁽²⁾ If parity protection is enabled for the peripheral SRAM modules, then the parity bits will also be initialized along with the SRAM modules.
- ⁽³⁾ The CPU RAM interface module has separate control bit-fields to select the memory power domain that is to be initialized.
- ⁽⁴⁾ The MibSPIx modules perform an initialization of the transmit and receive RAMs as soon as the multi-buffered mode is enabled. This is independent of whether the application has already initialized these RAMs using the auto-initialization method or not. The MibSPIx modules need to be released from reset by writing 1 to their SPIGCR0 registers before starting auto-initialization on their respective RAMs.

2.3 Exceptions

An “Exception” is an event that makes the processor temporarily halt the normal flow of program execution, for example, to service an interrupt from a peripheral. Before attempting to handle an exception, the processor preserves the critical parts of the current processor state so that the original program can resume when the handler routine has finished.

The following sections describe three exceptions – Reset, Abort and the System Software Interrupts.

For complete details on all exceptions, refer to the [ARM® Cortex®-R4F Technical Reference Manual](#).

2.3.1 Resets

The TMS570LS12x/11x microcontroller can be reset by either of the conditions described in [Table 2-8](#). Each reset condition is indicated in the System Exception Status Register (SYSESR).

The device nRST terminal is an I/O. It can be driven low by an external circuit to force a warm reset on the microcontroller. This terminal will be driven low as an output for a minimum of 32 peripheral clock (VCLK) cycles for any device system reset condition. As a result the EXTRST bit in the SYSESR register, SYSESR[3], gets set for all reset conditions listed in [Table 2-8](#). The nRST is driven low as an output for a longer duration during device power-up or whenever the power-on reset (nPORRST) is driven low externally. Refer the device datasheet for the electrical and timing specifications for the nRST.

Table 2-8. Causes of Resets

| Condition | Description |
|------------------------------------|---|
| Driving nPORRST pin low externally | Cold reset, or power-on reset. This reset signal is typically driven by an external voltage supervisor. This reset is flagged by the PORST bit in the SYSESR register, SYSESR[15]. |
| Voltage Monitor reset | The microcontroller has an embedded voltage monitor that generates a power-on reset when the core voltage gets out of a valid range, or when the I/O voltage falls below a threshold. This reset is also flagged by the PORST bit in the SYSESR register, SYSESR[15]. Note: The voltage monitor is not an alternative for an external voltage supervisor. |
| Driving nRST pin low externally | Warm reset. This reset input is typically used in a system with multiple ICs and which requires that the microcontroller also gets reset whenever the other IC detects a fault condition. This reset is flagged by the EXTRST bit in the SYSESR, register SYSESR[3]. |
| Oscillator failure | This reset is generated by the system module when the clock monitor detects an oscillator fail condition. Whether or not a reset is generated is also dictated by a register in the system module. This reset is flagged by the OSCRST bit in the SYSESR register, SYSESR[14]. |
| Software reset | This reset is generated by the application software writing a 1 to bit 15 of System Exception Control Register (SYSECR) or a 0 to bit 14 of SYSECR. It is typically used by a bootloader type of code that uses a software reset to allow the code execution to branch to the application code once it is programmed into the program memory. This reset is flagged by the SWRST bit in the SYSESR register, SYSESR[4]. |
| CPU reset | This reset is generated by the CPU self-test controller (LBIST) or by changing the memory protection (MMU/MPU) configuration in the CPURSTCR register. This reset is flagged by the CPURST bit in the SYSESR register, SYSESR[5]. |
| Debug reset | The debug logic implemented on the microcontroller allows a system reset to be generated. This reset is flagged by the DBGRST bit in the SYSESR register, SYSESR[13]. |
| Watchdog reset | This reset is generated by the digital windowed watchdog (DWWD) module on the microcontroller. The DWWD can generate a reset whenever the watchdog service window is violated. This reset is flagged by the WDRST bit in the SYSESR register, SYSESR[13]. |

2.3.2 Aborts

When the ARM Cortex-R4F processor's memory system cannot complete a memory access successfully, an abort is generated. An error occurring on an instruction fetch generates a **prefetch abort**. Errors occurring on data accesses generate **data aborts**. Aborts are also categorized as being either **precise** or **imprecise**.

2.3.2.1 Prefetch Aborts

When a Prefetch Abort (PABT) occurs, the processor marks the prefetched instruction as invalid, but does not take the exception until the instruction is to be executed. If the instruction is not executed, for example because a branch occurs while it is in the pipeline, the abort does not take place.

All prefetch aborts are precise aborts.

2.3.2.2 Data Aborts

An error occurring on a data memory access can generate a data abort. If the instruction generating the memory access is not executed, for example, because it fails its condition codes, or is interrupted, the data abort does not take place.

A Data Abort (DABT) can be either precise or imprecise, depending on the type of fault that caused it.

2.3.2.3 Precise Aborts

A precise abort, also known as a synchronous abort, is one for which the exception is guaranteed to be taken on the instruction that generated the aborting memory access. The abort handler can use the value in the Link Register (r14_abt) to determine which instruction generated the abort, and the value in the Saved Program Status Register (SPSR_abt) to determine the state of the processor when the abort occurred.

2.3.2.4 Imprecise Aborts

An imprecise abort, also known as an asynchronous abort, is one for which the exception is taken on a later instruction to the instruction that generated the aborting memory access. The abort handler cannot determine which instruction generated the abort, or the state of the processor when the abort occurred. Therefore, imprecise aborts are normally fatal.

Imprecise aborts can be generated by store instructions to normal-type or device-type memory. When the store instruction is committed, the data is normally written into a buffer that holds the data until the memory system has sufficient bandwidth to perform the write access. This gives read accesses higher priority. The write data can be held in the buffer for a long period, during which many other instructions can complete. If an error occurs when the write is finally performed, this generates an imprecise abort.

The TMS570LS12x/11x microcontroller architecture applies techniques at the system level to mitigate the impact of imprecise aborts. System level adoption of write status sidebands to the data path allow bus masters to comprehend imprecise aborts, turning them into precise aborts. In cases where this approach is not feasible, buffering bridges or other sources of imprecision may build a FIFO of current transactions such that an imprecise abort may be registered at the point of imprecision for later analysis.

Masking Of Imprecise Aborts:

The nature of imprecise aborts means that they can occur while the processor is handling a different abort. If an imprecise abort generates a new exception in such a situation, the banked link register (R14_abt) and the Saved Processor Status Register (SPSR_abt) values are overwritten. If this occurs before the data is pushed to the stack in memory, the state information about the first abort is lost. To prevent this from happening, the Current Processor Status Register (CPSR) contains a mask bit to indicate that an imprecise abort cannot be accepted, the A-bit. When the A-bit is set, any imprecise abort that occurs is held pending by the processor until the A-bit is cleared, when the exception is actually taken. The A-bit is automatically set when abort, IRQ or FIQ exceptions are taken, and on reset. The application must only clear the A-bit in an abort handler after the state information has either been stacked to memory, or is no longer required.

NOTE: Default Behavior for Imprecise Aborts

The A-bit in the CPSR is set by default. This means that no imprecise abort exception will occur. The application must enable imprecise abort exception generation by clearing the A-bit of the CPSR.

2.3.2.5 Conditions That Generate Aborts

An Abort is generated under the following conditions on the TMS570LS12x/11x microcontrollers.

- Access to an illegal address (a nonimplemented address)
- Access to a protected address (protection violation)
- Parity / ECC / Time-out Error on a valid access

Illegal Addresses:

The illegal addresses and the responses to an access to these addresses are defined in [Table 2-3](#).

Addresses Protected By MPU:

Memory access permissions can be configured via the ARM Cortex-R4F processor's Memory Protection Unit (MPU). For more details on the MPU configuration, refer to the [ARM® Cortex®-R4F Technical Reference Manual](#).

A memory access violation is logged as a permission fault in the CPU's fault status register and the virtual address of the access is logged into the CPU's fault address register.

Protection of Peripheral Register and Memory Frames:

Accesses to the peripheral register and memory frames can be protected either by configuring the MPU or by configuring the Peripheral Central Resource (PCR) controller registers.

The PCR module PPROTSETx registers contain one bit per peripheral select quadrant. These bits define the access permissions to the peripheral register frames. If the CPU attempts to write to a peripheral register for which it does not have the correct permissions, a protection violation is detected and an Abort occurs.

Some modules also enforce register updates to only be allowed when the CPU is in a privileged mode of operation. If the CPU writes to these registers in user mode, the writes are ignored.

The PCR module PMPROTSETx registers contain one bit per peripheral memory frame. These bits define the access permissions to the peripheral memory frames. If the CPU attempts to write to a peripheral memory for which it does not have the correct permissions, a protection violation is detected and an Abort occurs.

NOTE: No Access Protection for Reads

The PCR PPROTSETx and PMPROTSETx registers protect the peripheral registers and memories against illegal writes by the CPU. The CPU can read from the peripheral registers and memories in both user and privileged modes.

2.3.3 System Software Interrupts

The system module provides the capability of generating up to four software interrupts. A software interrupt is generated by writing the correct key value to either of the four System Software Interrupt Registers (SSIRx). The SSI registers also allow the application to provide a label for that software interrupt. This label is an 8-bit value that can then be used by the interrupt service routine to perform the required task based on the value provided. The source of the system software interrupt is reflected in the system software interrupt vector (SSIVEC) register.

2.4 Clocks

This section describes the clocking structure of the TMS570LS12x/11x microcontrollers.

2.4.1 Clock Sources

The devices support up to 7 clock sources. These are shown in [Table 2-9](#). The electrical specifications as well as timing requirements for each of the clock sources are specified in the device datasheet.

Table 2-9. Clock Sources

| Clock Source # | Clock Source Name | Description |
|----------------|--------------------------------|---|
| 0 | OSCM | Main oscillator. This is the primary clock for the microcontroller and is the only clock that is input to the phase-locked loops. The oscillator frequency must be between 5 and 20 MHz. |
| 1 | PLL1 | This is the output of the main PLL. The PLL is capable of modulating its output frequency in a controlled manner to reduce the radiated emissions. |
| 2 | Reserved | This clock source is not available and must not be enabled or used as source for any clock domain. |
| 3 | EXTCLKIN1 | External clock input 1. A square wave input can be applied to this device input and used as a clock source inside the device. |
| 4 | LF LPO (Low-Frequency LPO) | This is the low-frequency output of the internal reference oscillator. This is typically an 80 KHz signal which is used by the real-time interrupt module for generating periodic interrupts to wake up from a low power mode. |
| 5 | HF LPO (High-Frequency LPO) | This is the high-frequency output of the internal reference oscillator. This is typically a 10 MHz signal which is used by the clock monitor module as a reference clock to monitor the main oscillator frequency. |
| 6 | PLL2 | This is the output of the second PLL. There is no option of modulating this PLL's output signal. This separate non-modulating PLL allows the generation of an asynchronous clock source that is independent of the CPU clock frequency. |
| 7 | EXTCLKIN2 | External clock input 2. A square wave input can be applied to this device input and used as a clock source inside the device. |

2.4.1.1 Enabling / Disabling Clock Sources

Each clock source can be independently enabled or disabled using the set of Clock Source Disable registers – CSDIS, CSDISSET and CSDISCLR.

Each bit in these registers corresponds to the clock source number indicated in [Table 2-9](#). For example, setting bit 1 in the CSDIS or CSDISSET registers disables the PLL#1.

NOTE: Disabling the Main Oscillator or HF LPO

By default, the clock monitoring circuit is enabled and checks for the main oscillator frequency to be within a certain range using the HF LPO as a reference. If the main oscillator and/or the HF LPO are disabled with the clock monitoring still enabled, the clock monitor will indicate an oscillator fault. The clock monitoring must be disabled before disabling the main oscillator or the HF LPO clock source(s).

The clock source is only disabled once there is no active clock domain that is using that clock source. Also, see [Chapter 10](#) for more information on enabling/disabling the oscillator and PLL.

On the TMS570LS12x/11x microcontrollers, the clock sources 0, 4 and 5 are enabled by default.

2.4.1.2 Checking for Valid Clock Sources

The application can check whether a clock source is valid or not by checking the corresponding bit to be set in the Clock Source Valid Status (CSVSTAT) register. For example, the application can check if bit 1 in CSVSTAT is set before using the output of PLL#1 as the source for any clock domain.

2.4.2 Clock Domains

The clocking on this device is divided into multiple clock domains for flexibility in control as well as clock source selection. There are 10 clock domains on this device. Each of these are described in [Table 2-10](#).

Each of the control registers listed in [Table 2-10](#) are defined in [Section 2.5](#). The AC timing characteristics for each clock domain are specified in the device datasheet.

Table 2-10. Clock Domains

| Clock Domain # | Clock Domain | Default Source | Source Selection Register | Special Considerations |
|----------------|--------------|----------------|---------------------------|--|
| 0 | GCLK | OSCIN | GHVSR | <ul style="list-style-type: none"> • Clock domain used by one of the two Cortex-R4F CPUs operating in lock-step • Always the same frequency as HCLK • In phase with HCLK • Is disabled separately from HCLK via the CDDISx registers bit 0 • Can be divided by 1 up to 8 when running CPU selftest (LBIST) using the CLKDIV field of the STCCLKDIV register at address 0xFFFFE108 |
| 0 | GCLK2 | OSCIN | GHVSR | <ul style="list-style-type: none"> • Clock domain used by the second Cortex-R4F CPU operating in lock-step • Always the same frequency as GCLK • 2 cycles delayed from GCLK • Is disabled along with GCLK • Gets divided by the same divider setting as that for GCLK when running CPU selftest (LBIST) |
| 1 | HCLK | OSCIN | GHVSR | <ul style="list-style-type: none"> • Clock domain used by the high-speed system modules: Flash memory interfaces, TCRAM interface, Error Signaling Module (ESM), DMA • Is disabled via the CDDISx registers bit 1 |
| 2 | VCLK | OSCIN | GHVSR | <ul style="list-style-type: none"> • Clock domain used by some system modules (VIM), peripheral modules accessed via the Peripheral Central Resource (PCR) controller, and all other register interfaces also accessed via the PCR • Divided down from HCLK • Can be HCLK/1, HCLK/2,... or HCLK/16 • Is disabled separately from HCLK via the CDDISx registers bit 2 |
| 3 | VCLK2 | OSCIN | GHVSR | <ul style="list-style-type: none"> • Clock domain used by the timer modules: N2HET1, N2HET2 and the dedicated transfer units: HTU1, HTU2 • Divided down from HCLK • Can be HCLK/1, HCLK/2,... or HCLK/16 • Frequency must be an integer multiple of VCLK frequency • Is disabled separately from HCLK via the CDDISx registers bit 3 |
| 8 | VCLK3 | OSCIN | GHVSR | <ul style="list-style-type: none"> • Clock domain used for EMAC and EMIF slave interfaces • Divided down from HCLK • Can be HCLK/1, HCLK/2,... or HCLK/16 • Is disabled separately from HCLK via the CDDISx registers bit 8 |
| | VCLK4 | OSCIN | GHVSR | <ul style="list-style-type: none"> • Clock domain used for ePWM, eCAP, and eQEP modules • Divided down from HCLK • Can be HCLK/1, HCLK/2,... or HCLK/16 • Is disabled separately from HCLK via the CDDISx registers bit 9 |
| 4 | VCLKA1 | VCLK | VCLKASR | <ul style="list-style-type: none"> • Clock domain dedicated for the CAN controllers: DCAN1, DCAN2, DCAN3, used for baud-rate generation • Defaults to VCLK as the source • Frequency can be as fast as HCLK frequency • Is disabled via the CDDISx registers bit 4 |

Table 2-10. Clock Domains (continued)

| Clock Domain # | Clock Domain | Default Source | Source Selection Register | Special Considerations |
|----------------|--------------|----------------|---------------------------|---|
| 5 | VCLKA2 | VCLK | VCLKASRC | <ul style="list-style-type: none"> • Clock domain dedicated for the FlexRay controller and the dedicated transfer unit • Defaults to VCLK as the source • Frequency can be as fast as HCLK frequency • Is disabled via the CDDISx registers bit 5 |
| 11 | VCLKA4 | VCLK | VCLKACON1 | <ul style="list-style-type: none"> • Clock domain dedicated for the Ethernet controller (EMAC) when the TX and RX clocks are internally generated • Defaults to VCLK as the source • Frequency can be as fast as HCLK frequency • Is disabled via the CDDISx registers bit 11 |
| 11 | VCLKA4_DIVR | VCLK | VCLKACON1 | <ul style="list-style-type: none"> • Divided down from VCLKA4 using the VCLKA4R field of the VCLKACON1 register • Frequency can be VCLKA4/1, VCLKA4/2, ..., or VCLKA4/8 • Default frequency is VCLKA4/2 • Is disabled separately via the VCLKACON1 register's VCLKA4_DIV_CDDIS bit, if the VCLKA4 is not already disabled |
| 6 | RTICKL | VCLK | RCLKSRC | <ul style="list-style-type: none"> • Clock domain dedicated for timebase generation in the Real-Time Interrupt (RTI) generation module • Defaults to VCLK as the source • If a clock source other than VCLK is selected for RTICKL, then the RTICKL frequency must be less than or equal to VCLK/3 • Application can ensure this by programming the RTI1DIV field of the RCLKSRC register, if necessary • Is disabled via the CDDISx registers bit 6 |

2.4.2.1 Enabling / Disabling Clock Domains

Each clock domain can be independently enabled or disabled using the set of Clock Domain Disable registers – CDDIS, CDDISSET and CDDISCLR.

Each bit in these registers corresponds to the clock domain number indicated in [Table 2-10](#). For example, setting bit 1 in the CDDIS or CDDISSET registers disables the HCLK clock domain. The clock domain will be turned off only when every module that uses the HCLK domain gives the “permission” for HCLK to be turned off.

All clock domains are enabled by default, or upon a system reset, or whenever a wake up condition is detected.

2.4.2.2 Mapping Clock Sources to Clock Domains

Each clock domain needs to be mapped to a valid clock source. There are control registers that allow an application to choose the clock sources for each clock domain.

- **Selecting clock source for GCLK, HCLK and VCLKx domains**

The CPU clock (GCLK), the system module clock (HCLK), and the peripheral bus clocks (VCLKx) all use the same clock source. This clock source is selected via the GHVSRC register. The default source for the GCLK, HCLK and VCLKx is the main oscillator. That is, after power up, the GCLK and HCLK are running at the OSCIN frequency, while the VCLKx frequency is the OSCIN frequency divided by 2.

- **Selecting clock source for VCLKA1 and VCLKA2 domains**

The clock source for VCLKA1 and VCLKA2 domains is selected via the VCLKASRC register. The default source for the VCLKA1 and VCLKA2 domains is the VCLK.

- **Selecting clock source for VCLKA4 domain**

The clock source for VCLKA4 domain is selected via the VCLKACON1 register. The default source for the VCLKA4 domain is the VCLK.

- **Selecting clock source for RTICLK domain**

The clock source for RTICLK domain is selected via the RCLKSRC register. The default source for the RTICLK domain is the VCLK.

NOTE: Selecting a clock source for RTICLK that is not VCLK

When the application chooses a clock source for RTICLK domain that is not VCLK, then the application must ensure that the resulting RTICLK frequency must be less than or equal to VCLK frequency divided by 3. The application can configure the RTI1DIV field of the RCLKSRC register for dividing the selected clock source frequency by 1, 2, 4 or 8 to meet this requirement.

2.4.3 Low Power Modes

All clock domains are active in the normal operating mode. This is the default mode of operation. As described in [Section 2.4.1.1](#) and [Section 2.4.2.1](#), the application can choose to disable any particular clock source and domain that it does not plan to use. Also, the peripheral central resource controller (PCR) has control registers to enable / disable the peripheral clock (VCLK) for each peripheral select. This offers the application a large number of choices for enabling / disabling clock sources, or clock domains, or clocks to specific peripherals.

This section describes three particular low-power modes and their typical characteristics. They are not the only low-power modes configurable by the application, as just described.

Table 2-11. Typical Low-Power Modes

| Mode Name | Active Clock Source(s) | Active Clock Domain(s) | Wake Up Options | Suggested Wake Up Clock Source(s) | Wake Up Time(wake up detected -to- CPU code execution start) |
|-----------|------------------------|------------------------|---|-----------------------------------|--|
| Doze | Main oscillator | RTICK | RTI interrupt, GIO interrupt, CAN message, SCI message | Main oscillator | Flash pump sleep -> standby transition time + Flash bank sleep -> standby transition time + Flash bank standby -> active transition time |
| Snooze | LF LPO | RTICK | RTI interrupt, GIO interrupt, CAN message, SCI message | HF LPO | HF LPO warm start-up time + Flash pump sleep -> standby transition time + Flash bank sleep -> standby transition time + Flash bank standby -> active transition time |
| Sleep | None | None | GIO interrupt, CAN message, SCI message | HF LPO | HF LPO warm start-up time + Flash pump sleep -> standby transition time + Flash bank sleep -> standby transition time + Flash bank standby -> active transition time |

2.4.3.1 Typical Software Sequence to Enter a Low-Power Mode

1. Program the flash banks and flash pump fall-back modes to be “sleep”.

The flash pump transitions from active to sleep mode only after all the flash banks have switched from active to sleep mode. The flash banks start switching from active to sleep mode only after the banks are not accessed for at least a duration defined by the Active Grace Period (AGP) parameter configured for the banks. See [Chapter 5](#) for more details.

2. Disable the clock sources that are not required to be kept active.

A clock source does not get disabled until all clock domains using that clock source are disabled first, or are configured to use an alternate clock source.

3. Disable the clock domains that are not required to be kept active.

A clock domain does not get disabled until all modules using that clock domain “give their permission” for that clock domain to be turned off.

4. Idle the Cortex-R4F core.

The ARM Cortex-R4F CPU has internal power management logic, and requires a dedicated instruction to be used in order to enter a low power mode. This is the Wait For Interrupt (WFI) instruction.

When a WFI instruction is executed, the Cortex-R4F core flushes its pipeline, flushes all write buffers, and completes all pending bus transactions. At this time the core indicates to the system that the clock to the core can be stopped. This indication is used by the Global Clock Module (GCM) to turn off the CPU clock domain (GCLK) if the CDDIS register bit 0 is set.

2.4.3.2 Special Considerations for Entry to Low Power Modes

Some bus master modules – High-End Timer Transfer Units (HTUx), FlexRay Transfer Unit (FTU), and Parameter Overlay Module (POM), can have ongoing transactions when the application wants to enter a low power mode to turn off the clocks to those modules. This is not recommended as it could leave the device in an unpredictable state. Refer to the individual module user guides for more information about the sequence to be followed to safely enter a low-power mode.

2.4.3.3 Selecting Clock Source Upon Wake Up

The domains for CPU clock (GCLK), the system clock (HCLK) and the peripheral clock (VCLKx) use the same clock source selected via the GHVSRC field of the GHVSRC register. The GHVSRC register also allows the application to choose the clock source after wake up via the GHVWAKE field.

When a wake up condition is detected, if the selected wake up clock source is not already active, the global clock module (GCM) will enable this selected clock source, wait for it to become valid, and then use it for the GCLK, HCLK and VCLKx domains. The other clock domains VCLKAx and RTICLK retain the configuration for their clock source selection registers – VCLKASRC, VCLKACON1 and RCLKSRC.

2.4.4 Clock Test Mode

The TMS570LS12x/11x microcontrollers support a test mode which allows a user to bring out several different clock sources and clock domains on to the ECLK terminal. This is very useful information for debug purposes. Each clock source also has a corresponding clock source valid status flag in the Clock Source Valid Status (CSVSTAT) register. The clock source valid status flags can also be brought out on to the N2HET1[12] terminal in this clock test mode.

The clock test mode is controlled by the CLKTEST register ([Section 2.5.1.32](#)) in the system module register frame.

The clock test mode is enabled by writing 5h to the CLK_TEST_EN field.

The signal to be brought out on to the ECLK terminal is defined by the SEL_ECP_PIN field and the signal to be brought out on to the N2HET1[12] terminal is defined by the SEL_GIO_PIN field.

The choices for these selections are defined in [Table 2-12](#).

Table 2-12. Clock Test Mode Options

| SEL_ECP_PIN | Signal on ECLK | SEL_GIO_PIN | Signal on N2HET1[12] |
|-------------|--|-------------|-------------------------|
| 0000 | Oscillator | 0000 | Oscillator Valid status |
| 0001 | PLL1 free-running clock output | 0001 | PLL1 Valid status |
| 0010 | Reserved | 0010 | Reserved |
| 0011 | EXTCLKIN1 | 0011 | Reserved |
| 0100 | Low-frequency LPO (Low-Power Oscillator) clock | 0100 | Reserved |
| 0101 | High-frequency LPO (Low-Power Oscillator) clock | 0101 | HF LPO Valid status |
| 0110 | PLL2 free-running clock output | 0110 | PLL2 Valid Status |
| 0111 | EXTCLKIN2 | 0111 | Reserved |
| 1000 | GCLK | 1000 | LF LPO Valid status |
| 1001 | RTI Base | 1001 | Oscillator Valid status |
| 1010 | Reserved | 1010 | Oscillator Valid status |
| 1011 | VCLKA1 | 1011 | Oscillator Valid status |
| 1100 | VCLKA2 | 1100 | Oscillator Valid status |
| 1101 | Reserved | 1101 | Reserved |
| 1110 | VCLKA4_DIVR | 1110 | VCLKA4 |
| 1111 | Reserved | 1111 | Oscillator Valid status |

2.4.5 Safety Considerations for Clocks

The TMS570LS12x/11x microcontrollers are targeted for use in several safety-critical applications. The following sections describe the internal or external monitoring mechanisms that detect and signal clock source failures.

2.4.5.1 Oscillator Monitor

The oscillator clock frequency is monitored by a dedicated circuitry called CLKDET using the HF LPO as the reference clock. The CLKDET flags an oscillator fail condition whenever the OSCIN frequency falls outside of a range which is defined by the HF LPO frequency.

The valid OSCIN range is defined as a minimum of $f_{(\text{HF LPO})} / 4$ to a maximum of $f_{(\text{HF LPO})} \times 4$.

The untrimmed HF LPO frequency on this device can range from 5.5MHz to 19.5MHz. This results in a valid OSCIN frequency range depicted in [Figure 2-4](#).

The application can select the device response to an oscillator fail indication. See [Chapter 10](#) for more details on the oscillator monitoring and the system response choices.

Figure 2-4. LPO and Clock Detection, Untrimmed HF LPO

2.4.5.2 PLL Slip Detector

Both the PLL macros implemented on the microcontrollers have an embedded slip detection circuit. A PLL slip is detected by the slip detector under the following conditions:

1. Reference cycle slip, RFSLIP — the output clock is running *too fast* relative to the reference clock
2. Feedback cycle slip, FBSLIP — the output clock is running *too slow* relative to the reference clock

The device also includes optional filters that can be enabled before a slip indication from the PLL is actually logged in the system module Global Status Register (GLBSTAT). Also, once a PLL slip condition is logged in the system module global status register, the application can choose the device's response to the slip indication. Refer to the Oscillator and PLL chapter for more details on PLL slip and the system response choices.

2.4.5.3 External Clock Monitor

The microcontrollers support a terminal called ECLK – External Clock, which is used to output a slow frequency which is divided down from the device system clock frequency. An external circuit can monitor the ECLK frequency in order to check that the device is operating at the correct frequency.

The frequency of the signal output on the ECLK pin can be divided down by 1 to 65536 from the peripheral clock (VCLK) frequency using the External Clock Prescaler Control Register (ECPCNTL). The actual clock output on ECLK is enabled by setting the ECP CLK FUN bit of the SYSPC1 control register.

2.4.5.4 Dual-Clock Comparators

The microcontrollers include two instances of the dual-clock comparator module. This module includes two down counters which independently count from two separate seed values at the rate of two independent clock frequencies. One of the clock inputs is a reference clock input, selectable between the main oscillator or the HF LPO in functional mode. The second clock input is selectable from among a set of defined signals as described in [Section 2.4.5.4.1](#) and [Section 2.4.5.4.2](#). This mechanism can be used to use a known-good clock to measure the frequency of another clock.

2.4.5.4.1 DCC1

Table 2-13. DCC1 Counter 0 Clock Inputs

| Clock Source [3-0] | Clock / Signal Name |
|--------------------|---------------------|
| others | oscillator (OSCIN) |
| 0x5 | HF LPO |
| 0xA | test clock (TCK) |

Table 2-14. DCC1 Counter 1 Clock / Signal Inputs

| Key [3-0] | Clock Source [3-0] | Clock / Signal Name |
|-----------|--------------------|--------------------------|
| 0xA | 0x0 | PLL1 free-running output |
| | 0x1 | PLL2 free-running output |
| | 0x2 | LF LPO |
| | 0x3 | HF LPO |
| | 0x4 | Reserved |
| | 0x5 | EXTCLKIN1 |
| | 0x6 | EXTCLKIN2 |
| | 0x7 | Reserved |
| | 0x8-0xF | VCLK |
| others | any value | N2HET1[31] |

As can be seen, the main oscillator (OSCIN) can be used for counter 0 as a “known-good” reference clock. The clock for counter 1 can be selected from among 8 options. See [Chapter 11](#) for more details on the DCC usage.

2.4.5.4.2 DCC2

Table 2-15. DCC2 Counter 0 Clock Inputs

| Clock Source [3-0] | Clock / Signal Name |
|--------------------|---------------------|
| others | oscillator (OSCIN) |
| 0xA | test clock (TCK) |

Table 2-16. DCC2 Counter 1 Clock / Signal Inputs

| Key [3-0] | Clock Source [3-0] | Clock / Signal Name |
|-----------|--------------------|---------------------|
| 0xA | 0x0-0x7 | Reserved |
| | 0x8-0xF | VCLK |
| others | any value | N2HET2[0] |

As can be seen, the main oscillator (OSCIN) can be used for counter 0 as a “known-good” reference clock. The clock for counter 1 can be selected from among 2 options. See [Chapter 11](#) for more details on the DCC usage.

2.5 System and Peripheral Control Registers

The following sections describe the system and peripheral control registers of the TMS570LS12x/11x microcontroller.

2.5.1 Primary System Control Registers (SYS)

This section describes the SYSTEM registers. These registers are divided into two separate frames. The start address of the primary system module frame is FFFF FF00h. The start address of the secondary system module frame is FFFF E100h. The registers support 32-, 16-, and 8-bit writes. The offset is relative to the system module frame start address.

Table 2-17 contains a list of the primary system control registers.

Table 2-17. Primary System Control Registers

| Offset | Acronym | Register Description | Section |
|---------|-------------|--|----------------------------------|
| 00h | SYSPC1 | SYS Pin Control Register 1 | Section 2.5.1.1 |
| 04h | SYSPC2 | SYS Pin Control Register 2 | Section 2.5.1.2 |

2.5.1.1 SYS Pin Control Register 1 (SYSPC1)

The SYSPC1 register, shown in [Figure 2-5](#) and described in [Table 2-18](#), controls the function of the ECLK pin.

Figure 2-5. SYS Pin Control Register 1 (SYSPC1) [offset = 00]

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 2-18. SYS Pin Control Register 1 (SYSPC1) Field Descriptions

| Bit | Field | Value | Description |
|------|-----------|-------|--|
| 31-1 | Reserved | 0 | Read returns 0. Writes have no effect. |
| 0 | ECPCLKFUN | 0 | ECLK function. This bit changes the function of the ECLK pin. ECLK is in GIO mode. |
| | | 1 | ECLK is in functional mode as a clock output. Note: Proper ECLK duty cycle is not assured until 1 ECLK cycle has elapsed after switching into functional mode. |

2.5.1.2 SYS Pin Control Register 2 (SYSPC2)

The SYSPC2 register, shown in [Figure 2-6](#) and described in [Table 2-19](#), controls whether the pin is an input or an output when in GIO mode.

Figure 2-6. SYS Pin Control Register 2 (SYSPC2) [offset = 04h]

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 2-19. SYS Pin Control Register 2 (SYSPC2) Field Descriptions

| Bit | Field | Value | Description |
|------|-----------|-------|--|
| 31-1 | Reserved | 0 | Read returns 0. Writes have no effect. |
| 0 | ECPCLKDIR | 0 | ECLK data direction. This bit controls the direction of the ECLK pin when it is configured to be in GIO mode only. The ECLK pin is an input. Note: If the pin direction is set as an input, the output buffer is tristated. |
| | | 1 | The ECLK pin is an output. Note: The ECLK pin is placed into GIO mode by clearing the ECPCLKFUN bit to 0 in the SYSPC1 register. |

2.5.1.3 SYS Pin Control Register 3 (SYSPC3)

The SYSPC3 register, shown in [Figure 2-7](#) and described in [Table 2-20](#), displays the logic state of the ECLK pin when it is in GIO mode.

Figure 2-7. SYS Pin Control Register 3 (SYSPC3) [offset = 08h]

| | | | | | | | | | | | | | | | | |
|-----|----------|--|--|--|--|--|--|--|--|--|-----------|---|--|--|--|----|
| 31 | Reserved | | | | | | | | | | | | | | | 16 |

| 15 | Reserved | | | | | | | | | | 1 | 0 | | | | |
| R-0 | | | | | | | | | | | ECPCLKDIN | | | | | |
| R-0 | | | | | | | | | | | R-U | | | | | |

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset; -U = Undefined

Table 2-20. SYS Pin Control Register 3 (SYSPC3) Field Descriptions

| Bit | Field | Value | Description |
|------|-----------|-------|--|
| 31-1 | Reserved | 0 | Read returns 0. Writes have no effect. |
| 0 | ECPCLKDIN | 0 | ECLK data in. This bit displays the logic state of the ECLK pin when it is configured to be in GIO mode. |
| | | 0 | The ECLK pin is at logic low (0). |
| | | 1 | The ECLK pin is at logic high (1). |

2.5.1.4 SYS Pin Control Register 4 (SYSPC4)

The SYSPC4 register, shown in [Figure 2-8](#) and described in [Table 2-21](#), controls the logic level output function of the ECLK pin when it is configured as an output in GIO mode.

Figure 2-8. SYS Pin Control Register 4 (SYSPC4) [offset = 0Ch]

| | | | | | | | | | | | | | | | | |

| R-0 | | | | | | | | | | | R/W-0 | | | | | |

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 2-21. SYS Pin Control Register 4 (SYSPC4) Field Descriptions

| Bit | Field | Value | Description |
|------|------------|-------|---|
| 31-1 | Reserved | 0 | Read returns 0. Writes have no effect. |
| 0 | ECPCLKDOUT | | ECLK data out write. This bit is only active when the ECLK pin is configured to be in GIO mode. Writes to this bit will only take effect when the ECLK pin is configured as an output in GIO mode. The current logic state of the ECLK pin will be displayed by this bit in both input and output GIO mode. |
| | | 0 | The ECLK pin is driven to logic low (0). |
| | | 1 | The ECLK pin is driven to logic high (1). |
| | | | Note: The ECLK pin is placed into GIO mode by setting the ECPCLKFUN bit to 0 in the SYSPC1 register. The ECLK pin is placed in output mode by setting the ECPCLKDIR bit to 1 in the SYSPC2 register. |

2.5.1.5 SYS Pin Control Register 5 (SYSPC5)

The SYSPC5 register, shown in [Figure 2-9](#) and described in [Table 2-22](#), controls the set function of the ECLK pin when it is configured as an output in GIO mode.

Figure 2-9. SYS Pin Control Register 5 (SYSPC5) [offset = 10h]

| | | | | | | | | | | | | | | | | |

Table 2-22. SYS Pin Control Register 5 (SYSPC5) Field Descriptions

| Bit | Field | Value | Description |
|------|----------|-------|---|
| 31-1 | Reserved | 0 | Read returns 0. Writes have no effect. |
| 0 | ECPLKSET | 0 | ECLK data out set. This bit drives the output of the ECLK pin high when set in GIO output mode. <i>Write:</i> Writing a 0 has no effect. |
| | | 1 | <i>Write:</i> The ECLK pin is driven to logic high (1). Note: The current logic state of the ECPLKDOUT bit will also be displayed by this bit when the pin is configured in GIO output mode. Note: The ECLK pin is placed into GIO mode by setting the ECPLKFUN bit to 0 in the SYSPC1 register. The ECLK pin is placed in output mode by setting the ECPLKDIR bit to 1 in the SYSPC2 register. |

2.5.1.6 SYS Pin Control Register 6 (SYSPC6)

The SYSPC6 register, shown in [Figure 2-10](#) and described in [Table 2-23](#), controls the clear function of the ECLK pin when it is configured as an output in GIO mode..

Figure 2-10. SYS Pin Control Register 6 (SYSPC6) [offset = 14h]

| | | | | | | | | | | | | | | | | |

| R-0 | | | | | | | | | | | | | R/W-0 | | | |

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 2-23. SYS Pin Control Register 6 (SYSPC6) Field Descriptions

| Bit | Field | Value | Description |
|------|----------|-------|--|
| 31-1 | Reserved | 0 | Read returns 0. Writes have no effect. |
| 0 | ECPLKCLR | 0 | ECLK data out clear. This bit drives the output of the ECLK pin low when set in GIO output mode. <i>Write:</i> The ECLK pin value is unchanged. |
| | | 1 | <i>Write:</i> The ECLK pin is driven to logic low (0). Note: The current logic state of the ECPLKDOUT bit will also be displayed by this bit when the pin is configured in GIO output mode. Note: The ECLK pin is placed into GIO mode by setting the ECPLKFUN bit to 0 in the SYSPC1 register. The ECLK pin is placed in output mode by setting the ECPLKDIR bit to 1 in the SYSPC2 register. |

2.5.1.7 SYS Pin Control Register 7 (SYSPC7)

The SYSPC7 register, shown in [Figure 2-11](#) and described in [Table 2-24](#), controls the open drain function of the ECLK pin.

Figure 2-11. SYS Pin Control Register 7 (SYSPC7) [offset = 18h]

| | | | | | | | | | | | | | | | |

| R-0 | | | | | | | | | | | ECPCLKODE | | | | |
| R-0 | | | | | | | | | | | R/W-0 | | | | |

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 2-24. SYS Pin Control Register 7 (SYSPC7) Field Descriptions

| Bit | Field | Value | Description |
|------|-----------|-------|---|
| 31-1 | Reserved | 0 | Read returns 0. Writes have no effect. |
| 0 | ECPCLKODE | 0 | ECLK open drain enable. This bit is only active when ECLK is configured to be in GIO mode. |
| | | 0 | The ECLK pin is configured in push/pull (normal GIO) mode. |
| | | 1 | The ECLK pin is configured in open drain mode. The ECPCLKDOUT bit in the SYSPC4 register controls the state of the ECLK output buffer: ECPCLKDOUT = 0 The ECLK output buffer is driven low ECPCLKDOUT = 1 The ECLK output buffer is tristated |
| | | | Note: The ECLK pin is placed into GIO mode by setting the ECPCLKFUN bit to 0 in the SYSPC1 register. |

2.5.1.8 SYS Pin Control Register 8 (SYSPC8)

The SYSPC8 register, shown in [Figure 2-12](#) and described in [Table 2-25](#), controls the pull enable function of the ECLK pin when it is configured as an input in GIO mode.

Figure 2-12. SYS Pin Control Register 8 (SYSPC8) [offset = 1Ch]

| | | | | | | | | | | | | | | | |

| R-0 | | | | | | | | | | | R/W-D | | | | |

LEGEND: R/W = Read/Write; R = Read only; D = Device Specific; -n = value after reset

Table 2-25. SYS Pin Control Register 8 (SYSPC8) Field Descriptions

| Bit | Field | Value | Description |
|------|-----------|-------|--|
| 31-1 | Reserved | 0 | Read returns 0. Writes have no effect. |
| 0 | ECPCLKPUE | 0 | ECLK pull enable. Writes to this bit will only take effect when the ECLK pin is configured as an input in GIO mode. |
| | | 0 | ECLK pull enable is active. |
| | | 1 | ECLK pull enable is inactive. |
| | | | Note: The pull direction (up/down) is selected by the ECPCLKPS bit in the SYSPC9 register. |
| | | | Note: The ECLK pin is placed into GIO mode by setting the ECPCLKFUN bit to 0 in the SYSPC1 register. The ECLK pin is placed in input mode by setting the ECPCLKDIR bit to 0 in the SYSPC2 register. |

2.5.1.9 SYS Pin Control Register 9 (SYSPC9)

The SYSPC9 register, shown in [Figure 2-13](#) and described in [Table 2-26](#), controls the pull up/pull down configuration of the ECLK pin when it is configured as an input in GIO mode.

Figure 2-13. SYS Pin Control Register 9 (SYSPC9) [offset = 20h]

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 2-26. SYS Pin Control Register 9 (SYSPC9) Field Descriptions

| Bit | Field | Value | Description |
|------|----------|-------|--|
| 31-1 | Reserved | 0 | Read returns 0. Writes have no effect. |
| 0 | ECPCLKPS | 0 | ECLK pull up/pull down select. This bit is only active when ECLK is configured as an input in GIO mode and the pull up/pull down logic is enabled. |
| | | 0 | ECLK pull down is selected, when pull up/pull down logic is enabled. |
| | | 1 | ECLK pull up is selected, when pull up/pull down logic is enabled. |
| | | | Note: The ECLK pin pull up/pull down logic is enabled by setting the ECPCLKPUE bit to 0 in the SYSPC8 register. |
| | | | Note: The ECLK pin is placed into GIO mode by setting the ECPCLKFUN bit to 0 in the SYSPC1 register. The ECLK pin is placed in input mode by setting the ECPCLKDIR bit to 0 in the SYSPC2 register. |

2.5.1.10 Clock Source Disable Register (CSDIS)

The CSDIS register, shown in Figure 2-14 and described in Table 2-27, controls and displays the state of the device clock sources.

Figure 2-14. Clock Source Disable Register (CSDIS) [offset = 30h]

| | | | | | | | |
|-----------|-----------|-----------|-----------|-----------|----------|-----------|-----------|

LEGEND: R/W = Read/Write; R = Read only; WP = Write in privileged mode only; -n = value after reset

Table 2-27. Clock Source Disable Register (CSDIS) Field Descriptions

| Bit | Field | Value | Description |
|------|---------------|--------|--|
| 31-8 | Reserved | 0 | Reads return 0. Writes have no effect. |
| 7-3 | CLKSR[7-3]OFF | 0 1 | Clock source[7-3] off. Clock source[7-3] is enabled. Clock source[7-3] is disabled. Note: On wakeup, only clock sources 0, 4, and 5 are enabled. |
| 2 | Reserved | | Reads return one. Writes have no effect. |
| 1-0 | CLKSR[1-0]OFF | 0 1 | Clock source[1-0] off. Clock source[1-0] is enabled. Clock source[1-0] is disabled. Note: On wakeup, only clock sources 0, 4, and 5 are enabled. |

Table 2-28. Clock Sources Table

| Clock Source # | Clock Source Name |
|----------------|---|
| Clock Source 0 | Oscillator |
| Clock Source 1 | PLL1 |
| Clock Source 2 | Not Implemented |
| Clock Source 3 | EXTCLKIN |
| Clock Source 4 | Low Frequency LPO (Low Power Oscillator) clock |
| Clock Source 5 | High Frequency LPO (Low Power Oscillator) clock |
| Clock Source 6 | PLL2 |
| Clock Source 7 | EXTCLKIN2 |

NOTE: Nonimplemented clock sources should not be enabled or used.

2.5.1.11 Clock Source Disable Set Register (CSDISSET)

The CSDISSET register, shown in [Figure 2-15](#) and described in [Table 2-29](#), sets clock sources to the disabled state.

Figure 2-15. Clock Source Disable Set Register (CSDISSET) [offset = 34h]

| | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |

Table 2-29. Clock Source Disable Set Register (CSDISSET) Field Descriptions

| Bit | Field | Value | Description |
|------|------------------|-------|--|
| 31-8 | Reserved | 0 | Reads return 0. Writes have no effect. |
| 7-3 | SETCLKSR[7-3]OFF | 0 | Set clock source[7-3] to the disabled state. <i>Read:</i> Clock source[7-3] is enabled. <i>Write:</i> Clock source[7-3] is unchanged. |
| | | 1 | <i>Read:</i> Clock source[7-3] is disabled. <i>Write:</i> Clock source[7-3] is set to the disabled state. Note: After a new clock source disable bit is set via the CSDISSET register, the new status of the bit will be reflected in the CSDIS register (offset 30h), the CSDISSET register (offset 34h) and the CSDISCLR register (offset 38h). |
| | | | |
| 2 | Reserved | | Reads return one. Writes have no effect. |
| 1-0 | SETCLKSR[1-0]OFF | 0 | Set clock source[1-0] to the disabled state. <i>Read:</i> Clock source[1-0] is enabled. <i>Write:</i> Clock source[1-0] is unchanged. |
| | | 1 | <i>Read:</i> Clock source[1-0] is disabled. <i>Write:</i> Clock source[1-0] is set to the disabled state. Note: After a new clock source disable bit is set via the CSDISSET register, the new status of the bit will be reflected in the CSDIS register (offset 30h), the CSDISSET register (offset 34h) and the CSDISCLR register (offset 38h). |
| | | | |

NOTE: A list of the available clock sources is shown in [Table 2-28](#).

2.5.1.12 Clock Source Disable Clear Register (CSDISCLR)

The CSDISCLR register, shown in [Figure 2-16](#) and described in [Table 2-30](#), clears clock sources to the enabled state.

Figure 2-16. Clock Source Disable Clear Register (CSDISCLR) [offset = 38h]

Table 2-30. Clock Source Disable Clear Register (CSDISCLR) Field Descriptions

| Bit | Field | Value | Description |
|------|------------------|-------|--|
| 31-8 | Reserved | 0 | Reads return 0. Writes have no effect. |
| 7-3 | CLRCLKSR[7-3]OFF | 0 | Enables clock source[7-3]. <i>Read:</i> Clock source[7-3] is disabled. <i>Write:</i> Clock source[7-3] is unchanged. |
| | | 1 | <i>Read:</i> Clock source[7-3] is enabled. <i>Write:</i> Clock source[7-3] is set to the enabled state. Note: After a new clock source disable bit is set via the CSDISSET register, the new status of the bit will be reflected in the CSDIS register (offset 30h), the CSDISSET register (offset 34h) and the CSDISCLR register (offset 38h). |
| 2 | Reserved | | Reads return 1. Writes have no effect. |
| 1-0 | CLRCLKSR[1-0]OFF | 0 | Enables clock source[1-0]. <i>Read:</i> Clock source[1-0] is disabled. <i>Write:</i> Clock source[1-0] is unchanged. |
| | | 1 | <i>Read:</i> Clock source[1-0] is enabled. <i>Write:</i> Clock source[1-0] is set to the enabled state. Note: After a new clock source disable bit is set via the CSDISSET register, the new status of the bit will be reflected in the CSDIS register (offset 30h), the CSDISSET register (offset 34h) and the CSDISCLR register (offset 38h). |

NOTE: A list of the available clock sources is shown in [Table 2-28](#).

2.5.1.13 Clock Domain Disable Register (CDDIS)

The CDDIS register, shown in [Figure 2-17](#) and described in [Table 2-31](#), controls the state of the clock domains.

NOTE: All the clock domains are enabled on wakeup.

The application should guarantee that when HCLK and VCLK_sys are turned off through the HCLKOFF bit, the GCLK domain is also turned off.

Figure 2-17. Clock Domain Disable Register (CDDIS) [offset = 3Ch]

Table 2-33. Clock Domain Disable Clear Register (CDDISCLR) Field Descriptions

| Bit | Field | Value | Description |
|-------|-----------------|-------|---|
| 31-12 | Reserved | 0 | Read returns 0. Writes have no effect. |
| 11 | CLRVLKA4OFF | 0 | Clear VCLKA4 domain. <i>Read:</i> The VCLKA4 domain is enabled. <i>Write:</i> The VCLKA4 domain is unchanged. |
| | | 1 | <i>Read:</i> The VCLKA4 domain is disabled. <i>Write:</i> The VCLKA4 domain is cleared to the enabled state. |
| 10 | Reserved | 0-1 | Reads return 0 or 1 and privilege mode writes allowed. |
| 9-8 | CLRVLK[4-3]OFF | 0 | Clear VCLK[4-3] domain. <i>Read:</i> The VCLK[4-3] domain is enabled. <i>Write:</i> The VCLK[4-3] domain is unchanged. |
| | | 1 | <i>Read:</i> The VCLK[4-3] domain is disabled. <i>Write:</i> The VCLK[4-3] domain is cleared to the enabled state. |
| 7 | Reserved | 0-1 | Reads return 0 or 1 and privilege mode writes allowed. |
| 6 | CLRRT1CLKOFF | 0 | Clear RTICK1 domain. <i>Read:</i> The RTICK1 domain is enabled. <i>Write:</i> The RTICK1 domain is unchanged. |
| | | 1 | <i>Read:</i> The RTICK1 domain is disabled. <i>Write:</i> The RTICK1 domain is cleared to the enabled state. |
| 5-4 | CLRVLKA[2-1]OFF | 0 | Clear VCLKA[2-1] domain. <i>Read:</i> The VCLKA[2-1] domain is enabled. <i>Write:</i> The VCLKA[2-1] domain is unchanged. |
| | | 1 | <i>Read:</i> The VCLKA[2-1] domain is disabled. <i>Write:</i> The VCLKA[2-1] domain is cleared to the enabled state. |
| 3 | CLRVLK2OFF | 0 | Clear VCLK2 domain. <i>Read:</i> The VCLK2 domain is enabled. <i>Write:</i> The VCLK2 domain is unchanged. |
| | | 1 | <i>Read:</i> The VCLK2 domain is disabled. <i>Write:</i> The VCLK2 domain is cleared to the enabled state. |

Table 2-33. Clock Domain Disable Clear Register (CDDISCLR) Field Descriptions (continued)

| Bit | Field | Value | Description |
|-----|-------------|-------|---|
| 2 | CLRVCLKPOFF | 0 | Clear VCLK_periph domain. <i>Read:</i> The VCLK_periph domain is enabled. <i>Write:</i> The VCLK_periph domain is unchanged. |
| | | 1 | <i>Read:</i> The VCLK_periph domain is disabled. <i>Write:</i> The VCLK_periph domain is cleared to the enabled state. |
| 1 | CLRHCLKOFF | 0 | Clear HCLK and VCLK_sys domains. <i>Read:</i> The HCLK and VCLK_sys domain is enabled. <i>Write:</i> The HCLK and VCLK_sys domain is unchanged. |
| | | 1 | <i>Read:</i> The HCLK and VCLK_sys domain is disabled. <i>Write:</i> The HCLK and VCLK_sys domain is cleared to the enabled state. |
| 0 | CLRGCLKOFF | 0 | Clear GCLK domain. <i>Read:</i> The GCLK domain is enabled. <i>Write:</i> The GCLK domain is unchanged. |
| | | 1 | <i>Read:</i> The GCLK domain is disabled. <i>Write:</i> The GCLK domain is cleared to the enabled state. |

2.5.1.16 GCLK, HCLK, VCLK, and VCLK2 Source Register (GHVSR)

The GHVSR register, shown in [Figure 2-20](#) and described in [Table 2-34](#), controls the clock source configuration for the GCLK, HCLK, VCLK and VCLK2 clock domains.

Figure 2-20. GCLK, HCLK, VCLK, and VCLK2 Source Register (GHVSR) [offset = 48h]

Clock source4 is the source for HCLK, VCLK, VCLK2 on wakeup. Clock source5 is the source for HCLK, VCLK, VCLK2 on wakeup. Clock source6 is the source for HCLK, VCLK, VCLK2 on wakeup. Clock source7 is the source for HCLK, VCLK, VCLK2 on wakeup. Reserved - These values should not be used. |
| 15-4 | Reserved | 0 | Read returns 0. Writes have no effect. |
| 3-0 | GHVSR | 0 1h 2h 3h 4h 5h 6h 7h 8h-Fh | GCLK, HCLK, VCLK, VCLK2 current source. Note: The GHVSR[3-0] bits are updated with the HVLPM[3-0] setting when GCLK is turned off, and are updated with the GHVWAKE[3-0] setting on system wakeup. Clock source0 is the source for GCLK, HCLK, VCLK, VCLK2 on wakeup. Clock source1 is the source for GCLK, HCLK, VCLK, VCLK2 on wakeup. Clock source2 is the source for GCLK, HCLK, VCLK, VCLK2 on wakeup. Clock source3 is the source for GCLK, HCLK, VCLK, VCLK2 on wakeup. Clock source4 is the source for GCLK, HCLK, VCLK, VCLK2 on wakeup. Clock source5 is the source for GCLK, HCLK, VCLK, VCLK2 on wakeup. Clock source6 is the source for GCLK, HCLK, VCLK, VCLK2 on wakeup. Clock source7 is the source for GCLK, HCLK, VCLK, VCLK2 on wakeup. Reserved - These values should not be used. |

2.5.1.18 RTI Clock Source Register (RCLKSRC)

The RCLKSRC register, shown in [Figure 2-22](#) and described in [Table 2-36](#), controls the RTI (Real Time Interrupt) clock source selection.

NOTE: Important constraint when the RTI clock source is not VCLK

If the RTIx clock source is chosen to be anything other than the default VCLK, then the RTI clock needs to be at least three times slower than the VCLK. This can be achieved by configuring the RTIxCLK divider in this register. This divider is internally bypassed when the RTIx clock source is VCLK.

Figure 2-22. RTI Clock Source Register (RCLKSRC) [offset = 50h]

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 2-37. Clock Source Valid Register (CSVSTAT) Field Descriptions

| Bit | Field | Value | Description |
|------|-------------|--------|---|
| 31-8 | Reserved. | 0 | Reads return 0. Writes have no effect. |
| 7-3 | CLKSR[7-3]V | 0 1 | Clock source[7-3] valid. Clock source[7-3] is not valid. Clock source[7-3] is valid. Note: If the valid bit of the source of a clock domain is not set (that is, the clock source is not fully stable), the respective clock domain is disabled by the Global Clock Module (GCM). |
| 2 | Reserved. | 0 | Reads return 0. Writes have no effect. |
| 1-0 | CLKSR[1-0]V | 0 1 | Clock source[1-0] valid. Clock source[1-0] is not valid. Clock source[1-0] is valid. Note: If the valid bit of the source of a clock domain is not set (that is, the clock source is not fully stable), the respective clock domain is disabled. |

NOTE: A list of the available clock sources is shown in [Table 2-28](#).

2.5.1.20 Memory Self-Test Global Control Register (MSTGCR)

The MSTGCR register, shown in [Figure 2-24](#) and described in [Table 2-38](#), controls several aspects of the PBIST (Programmable Built-In Self Test) memory controller.

Figure 2-24. Memory Self-Test Global Control Register (MSTGCR) [offset = 58h]

| | | | | | |
|----------|--|---------|----|--------------|----|
| 31 | | 24 | 23 | | 16 |
| Reserved | | | | MBIST_ALGSEL | |
| R-0 | | | | R/WP-0 | |
| 15 | | 10 | 9 | 8 | 7 |
| Reserved | | ROM_DIV | | Reserved | |

| | | | | 4 | 3 |
| | | | | MSTGENA | |
| | | | | R/WP-5h | |

LEGEND: R = Read only; R/W = Read/Write; WP = Write in privileged mode only; -n = value after reset

Table 2-38. Memory Self-Test Global Control Register (MSTGCR) Field Descriptions

| Bit | Field | Value | Description |
|-------|--------------|---|--|
| 31-24 | Reserved | 0 | Read returns 0. Writes have no effect. |
| 23-16 | MBIST_ALGSEL | 0 1h 2h 4h 8h 10h 20h 40h 80h | Selects different test algorithm for PBIST No Algorithm selected. Checkerboard has been selected. March 13N with background of all 0s and all 1s has been selected. March 11N with background of hex 5 and As has been selected. March 13N with backgrounds of hex 3 and Cs, hex 0F and F0s, and 69 and 96s has been selected. PMOS Open Address Decode has been selected. No Algorithm selected. No Algorithm selected. No Algorithm selected. |
| 15-10 | Reserved | 0 | Read returns 0. Writes have no effect. |
| 9-8 | ROM_DIV | 0 1h 2h 3h | Prescaler divider bits for ROM clock source. ROM clock source is HCLK divided by 1. PBIST will reset for 16 VBUS cycles. ROM clock source is HCLK divided by 2. PBIST will reset for 32 VBUS cycles. ROM clock source is HCLK divided by 4. PBIST will reset for 64 VBUS cycles. ROM clock source is HCLK divided by 8. PBIST will reset for 96 VBUS cycles. |
| 7-4 | Reserved | 0 | Read returns 0. Writes have no effect. |
| 3-0 | MSTGENA | Ah Others | Memory self-test controller global enable key Note: Enabling the MSTGENA key will generate a reset to the state machine of the selected PBIST controller. Memory self-test controller is enabled. Memory self-test controller is disabled. Note: It is recommended that a value of 5h be used to disable the memory self-test controller. This value will give maximum protection from a bit flip inducing event that would inadvertently enable the controller. |

2.5.1.21 Memory Hardware Initialization Global Control Register (MINITGCR)

The MINITGCR register, shown in [Figure 2-25](#) and described in [Table 2-39](#), enables automatic hardware memory initialization.

Figure 2-25. Memory Hardware Initialization Global Control Register (MINITGCR) [offset = 5Ch]

LEGEND: R/W = Read/Write; R = Read only; WP = Write in privileged mode only; -n = value after reset

Table 2-39. Memory Hardware Initialization Global Control Register (MINITGCR) Field Descriptions

| Bit | Field | Value | Description |
|------|-----------|--------------|--|
| 31-4 | Reserved | 0 | Read returns 0. Writes have no effect. |
| 3-0 | MINITGENA | Ah Others | Memory hardware initialization global enable key. Global memory hardware initialization is enabled. Global memory hardware initialization is disabled. Note: It is recommended that a value of 5h be used to disable memory hardware initialization. This value will give maximum protection from an event that would inadvertently enable the controller. |

2.5.1.22 MBIST Controller/ Memory Initialization Enable Register (MSINENA)

The MSINENA register, shown in [Figure 2-26](#) and described in [Table 2-40](#), enables PBIST controllers for memory self test and the memory modules initialized during automatic hardware memory initialization.

Figure 2-26. MBIST Controller/Memory Initialization Enable Register (MSINENA) [offset = 60h]

| | | |
|----|--------|----|
| 31 | MSIENA | 16 |
| | R/WP-0 | |
| 15 | MSIENA | 0 |
| | R/WP-0 | |

LEGEND: R/W = Read/Write; R = Read only; WP = Write in privileged mode only; -n = value after reset

Table 2-40. MBIST Controller/Memory Initialization Enable Register (MSINENA) Field Descriptions

| Bit | Field | Value | Description |
|------|--------|-------|---|
| 31-0 | MSIENA | 0 | <p>PBIST controller and memory initialization enable register. In memory self-test mode, all the corresponding bits of the memories to be tested should be set before enabling the global memory self-test controller key (MSTGENA) in the MSTGCR register (offset 58h). The reason for this is that MSTGENA, in addition to being the global enable for all individual PBIST controllers, is the source for the reset generation to all the PBIST controller state machines. Disabling the MSTGENA or MINITGENA key (by writing from Ah to any other value) will reset all the MSIENA[31-0] bits to their default values.</p> <p>In memory self-test mode (MSTGENA = Ah): PBIST controller [31-0] is disabled.</p> <p>In memory Initialization mode (MINITGENA = Ah): Memory module [31-0] auto hardware initialization is disabled.</p> |
| | | 1 | <p>In memory self-test mode (MSTGENA = 5h): PBIST controller [31-0] is enabled.</p> <p>In memory Initialization mode (MINITGENA = 5h): Memory module [31-0] auto hardware initialization is enabled.</p> <p>Note: Software should ensure that both the memory self-test global enable key (MSTGENA) and the memory hardware initialization global key (MINITGENA) are not enabled at the same time.</p> |

2.5.1.23 Memory Self-Test Fail Status Register (MSTFAIL)

The MSTFAIL register, shown in [Figure 2-27](#) and described in [Table 2-41](#), shows the fail status of the memory self-tests.

Figure 2-27. Memory Self-Test Fail Status Register (MSTFAIL) [offset = 64h]

LEGEND: R/W = Read/Write; R = Read only; WP = Write in privileged mode only; -n = value after reset

Table 2-41. Memory Self-Test Fail Status Register (MSTFAIL) Field Descriptions

| Bit | Field | Value | Description |
|------|-------|-------|--|
| 31-0 | MSTF | 0 | Memory self-test fail status bit. <i>Read:</i> PBIST controller [31-0] run did not fail. <i>Write:</i> A write of 0 has no effect. |
| | | 1 | <i>Read:</i> PBIST controller [31-0] run failed. <i>Write:</i> The bit is cleared to 0. Note: Disabling the MSTGENA key (by writing from Ah to any other value) will reset all the individual fail status bits to their default values. |

2.5.1.24 MSTC Global Status Register (MSTCGSTAT)

The MSTCGSTAT register, shown in [Figure 2-28](#) and described in [Table 2-42](#), shows the status of the memory hardware initialization and the memory self-test.

Figure 2-28. MSTC Global Status Register (MSTCGSTAT) [offset = 68h]

LEGEND: R/W = Read/Write; R = Read only; C = Clear; WP = Write in privileged mode only; -n = value after reset

Table 2-42. MSTC Global Status Register (MSTCGSTAT) Field Descriptions

| Bit | Field | Value | Description |
|------|----------|-------|---|
| 31-9 | Reserved | 0 | Read returns 0. Writes have no effect. |
| 8 | MINIDONE | 0 | Memory hardware initialization complete status. Note: Disabling the MINITGENA key (By writing from Ah to any other value) will clear the MINIDONE status bit to 0. Note: Individual memory initialization status is shown in the MINISTAT register. <i>Read:</i> Memory hardware initialization is not complete for all memory. <i>Write:</i> A write of 0 has no effect. |
| | | 1 | <i>Read:</i> Hardware initialization of all memory is completed. <i>Write:</i> The bit is cleared to 0. |
| 7-1 | Reserved | 0 | Read returns 0. Writes have no effect. |
| 0 | MSTDONE | 0 | Memory self-test run complete status. Note: Disabling the MSTGENA key (by writing from Ah to any other value) will clear the MSTDONE status bit to 0. <i>Read:</i> Memory self-test is not completed. <i>Write:</i> A write of 0 has no effect. |
| | | 1 | <i>Read:</i> Memory self-test is completed. <i>Write:</i> The bit is cleared to 0. |

Table 2-44. PLL Control Register 1 (PLLCTL1) Field Descriptions

| Bit | Field | Value | Description |
|-------|-----------|---|---|
| 31 | ROS | 0 1 | Reset on PLL Slip Do not reset system when PLL slip is detected Reset when PLL slip is detected Note: BPOS (Bits 30-29) must also be enabled for ROS to be enabled. |
| 30-29 | MASK_SLIP | 2h Others | Mask detection of PLL slip Bypass on PLL Slip is disabled. If a PLL Slip is detected no action is taken. Bypass on PLL Slip is enabled. If a PLL Slip is detected the device will automatically bypass the PLL and use the oscillator to provide the device clock. Note: If ROS (Bit 31) is set to 1, the device will be reset if a PLL Slip and the PLL will be bypassed after the reset occurs. |
| 28-24 | PLLDIV | 0 1h : 1Fh | PLL Output Clock Divider $R = PLLDIV + 1$ $f_{PLL\ CLK} = f_{post-ODCLK} / R$ $f_{PLL\ CLK} = f_{post-ODCLK} / 1$ $f_{PLL\ CLK} = f_{post-ODCLK} / 2$: $f_{PLL\ CLK} = f_{post-ODCLK} / 32$ |
| 23 | ROF | 0 1 | Reset on Oscillator Fail Do not reset system when oscillator is out of range. Reset when oscillator is out of range. |
| 22 | Reserved | 0 | Value has no effect on PLL operation. |
| 21-16 | REFCLKDIV | 0 1h : 3Fh | Reference Clock Divider $NR = REFCLKDIV + 1$ $f_{INT\ CLK} = f_{OSCIN} / NR$ $f_{INT\ CLK} = f_{OSCIN} / 1$ $f_{INT\ CLK} = f_{OSCIN} / 2$: $f_{INT\ CLK} = f_{OSCIN} / 64$ |
| 15-0 | PLLMUL | 100h : 5B00h 5C00h : FF00h | PLL Multiplication Factor $NF = (PLLMUL / 256) + 1$, valid multiplication factors are from 1 to 256. $f_{VCO\ CLK} = f_{INT\ CLK} \times NF$ $f_{VCO\ CLK} = f_{INT\ CLK} \times 1$: $f_{VCO\ CLK} = f_{INT\ CLK} \times 92$ $f_{VCO\ CLK} = f_{INT\ CLK} \times 93$: $f_{VCO\ CLK} = f_{INT\ CLK} \times 256$ |

2.5.1.27 PLL Control Register 2 (PLLCTL2)

The PLLCTL2 register, shown in [Figure 2-31](#) and described in [Table 2-45](#), controls the modulation characteristics and the output divider of the PLL.

Figure 2-31. PLL Control Register 2 (PLLCTL2) [offset = 74h]

| | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |

LEGEND: R/W = Read/Write; R = Read only; WP = Write in privileged mode only; -n = value after reset

Table 2-45. PLL Control Register 2 (PLLCTL2) Field Descriptions

| Bit | Field | Value | Description |
|-------|---------------|----------------------------|--|
| 31 | FMENA | 0 1 | Frequency Modulation Enable. Disable frequency modulation Enable frequency modulation |
| 30-22 | SPREADINGRATE | 0 1h : 1FFh | $NS = SPREADINGRATE + 1$ $f_{mod} = f_s = f_{INT\ CLK} / (2 \times NS)$ $f_{mod} = f_s = f_{INT\ CLK} / (2 \times 1)$ $f_{mod} = f_s = f_{INT\ CLK} / (2 \times 2)$: $f_{mod} = f_s = f_{INT\ CLK} / (2 \times 512)$ |
| 21 | Reserved | 0 | Value has no effect on PLL operation. |
| 20-12 | MULMOD | 0 8h 9h : 1FFh | Multiplier Correction when Frequency Modulation is enabled When FMENA = 0, MUL_when_MOD = 0; when FMENA = 1, MUL_when_MOD = (MULMOD / 256) No adder to NF MUL_when_MOD = 8/256 MUL_when_MOD = 9/256 : MUL_when_MOD = 511/256 |
| 11-9 | ODPLL | 0 1h : 7h | Internal PLL Output Divider. $OD = ODPLL + 1$ $f_{post-ODCLK} = f_{VCO\ CLK} / OD$ Note: PLL output clock is gated off if ODPLL is changed while the PLL is active. $f_{post-ODCLK} = f_{VCO\ CLK} / 1$ $f_{post-ODCLK} = f_{VCO\ CLK} / 2$: $f_{post-ODCLK} = f_{VCO\ CLK} / 8$ Note: PLL output clock is gated off, if ODPLL is changed while the PLL is active. |

Table 2-45. PLL Control Register 2 (PLLCTL2) Field Descriptions (continued)

| Bit | Field | Value | Description |
|-----|------------|-------|--|
| 8-0 | SPR_AMOUNT | | Spreading Amount. $NV = (SPR_AMOUNT + 1)/2048$ NV ranges from 1/2048 to 512/2048 Note that the PLL output clock is disabled for 1 modulation period if the SPR_AMOUNT field is changed while the frequency modulation is enabled. If frequency modulation is disabled and SPR_AMOUNT is changed, there is no effect on the PLL output clock. |
| | | 0 | NV = 1/2048 |
| | | 1h | NV = 2/2048 |
| | | : | : |
| | | 1FFh | NV = 512/2048 |

2.5.1.28 SYS Pin Control Register 10 (SYSPC10)

The SYSPC10 register, shown in [Figure 2-32](#) and described in [Table 2-46](#), controls the function of the ECPCLK slew mode.

Figure 2-32. SYS Pin Control Register 10 (SYSPC10) [offset = 78h]

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 2-46. SYS Pin Control Register 10 (SYSPC10) Field Descriptions

| Bit | Field | Value | Description |
|------|-------------|-------|--|
| 31-1 | Reserved | 0 | Read returns 0. Writes have no effect. |
| 0 | ECPCLK_SLEW | 0 | Fast mode is enabled; the normal output buffer is used for this pin. |
| | | 1 | Slow mode is enabled; slew rate control is used for this pin. |

2.5.1.29 Die Identification Register Lower Word (DIEIDL)

The DIEIDL register, shown in [Figure 2-33](#) and described in [Table 2-47](#), contains information about the die lot number, wafer number, and X, Y wafer coordinates.

Figure 2-33. Die Identification Register, Lower Word (DIEIDL) [offset = 7Ch]

| | | | | | |
|---------------------|----|----|---------------------|---------------------|----|
| 31 | | 24 | 23 | | 16 |
| WAFAER # | | | | Y WAFAER COORDINATE | |
| R-D | | | | R-D | |
| 15 | 12 | 11 | | | 0 |
| Y WAFAER COORDINATE | | | X WAFAER COORDINATE | | |
| R-D | | | R-D | | |

LEGEND: R = Read only; -n = value after reset; -D = device specific

Table 2-47. Die Identification Register, Lower Word (DIEIDL) Field Descriptions

| Bit | Field | Description |
|-------|---------------------|--|
| 31-24 | WAFAER # | These read-only bits contain the wafer number of the device. |
| 23-12 | Y WAFAER COORDINATE | These read-only bits contain the Y wafer coordinate of the device. |
| 11-0 | X WAFAER COORDINATE | These read-only bits contain the X wafer coordinate of the device. |

NOTE: Die Identification Information

The die identification information will vary from unit to unit. This information is programmed by TI as part of the initial device test procedure.

2.5.1.30 Die Identification Register Upper Word (DIEIDH)

The DIEIDH register, shown in [Figure 2-34](#) and described in [Table 2-48](#), contains information about the die lot number.

Figure 2-34. Die Identification Register, Upper Word (DIEIDH) [offset = 80h]

| | | | | | |
|----------|--|----|----|-------|----|
| 31 | | 24 | 23 | | 16 |
| Reserved | | | | LOT # | |
| R-0 | | | | R-D | |
| 15 | | | | | 0 |
| LOT # | | | | | |
| R-D | | | | | |

LEGEND: R/W = Read/Write; R = Read only; D = Value is device dependent; -n = value after reset

Table 2-48. Die Identification Register, Upper Word (DIEIDH) Field Descriptions

| Bit | Field | Description |
|-------|----------|---|
| 31-24 | Reserved | Reserved for TI use. Writes have no effect. |
| 23-0 | LOT # | This read-only register contains the device lot number. |

NOTE: Die Identification Information

The die identification information will vary from unit to unit. This information is programmed by TI as part of the initial device test procedure.

2.5.1.31 LPO/Clock Monitor Control Register (LPOMONCTL)

The LPOMONCTL register, shown in [Figure 2-35](#) and described in [Table 2-49](#), controls the Low Frequency (Clock Source 4) and High Frequency (Clock Source 5) Low Power Oscillator's trim values.

Figure 2-35. LPO/Clock Monitor Control Register (LPOMONCTL) [offset = 88h]

| | | | | | |
|----------|----|----|----|----|-------------|
| 31 | 25 | 24 | 23 | 17 | 16 |
| Reserved | | | | | BIAS ENABLE |

LEGEND: R/W = Read/Write; R = Read only; WP = Write in privileged mode only; -n = value after reset

Table 2-49. LPO/Clock Monitor Control Register (LPOMONCTL) Field Descriptions

| Bit | Field | Value | Description |
|-------|-----------------|-------|---|
| 31-25 | Reserved | 0 | Read returns 0. Writes have no effect. |
| 24 | BIAS ENABLE | 0 | Bias enable. The bias circuit inside the low-power oscillator (LPO) is disabled. |
| | | 1 | The bias circuit inside LPO is enabled. |
| 23-17 | Reserved | 0 | Read returns 0. Writes have no effect. |
| 16 | OSCFRQCONFIGCNT | 0 | Configures the counter based on OSC frequency. OSC freq is ≤ 20MHz |
| | | 1 | OSC freq is > 20MHz and ≤ 80MHz |
| 15-13 | Reserved | 0 | Read returns 0. Writes have no effect. |

Table 2-49. LPO/Clock Monitor Control Register (LPOMONCTL) Field Descriptions (continued)

| Bit | Field | Value | Description | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |

2.5.1.32 Clock Test Register (CLKTEST)

The CLKTEST register, shown in [Figure 2-36](#) and described in [Table 2-50](#), controls the clock signal that is supplied to the ECLK pin for test and debug purposes.

NOTE: Clock Test Register Usage

This register should only be used for test and debug purposes.

Figure 2-36. Clock Test Register (CLKTEST) [offset = 8Ch]

| | | | | |
|----------|----|-----------------------|------------------|---------------------|

LEGEND: R/W = Read/Write; R = Read only; WP = Write in privileged mode only; -n = value after reset

Table 2-50. Clock Test Register (CLKTEST) Field Descriptions

| Bit | Field | Value | Description |
|-------|-------------------|--------------|--|
| 31-27 | Reserved | 0 | Read returns 0. Writes have no effect. |
| 26 | ALTLMPCLOCKENABLE | 0 1 | This bit selects a clock driven by the GIOB[0] pin as an alternate limp clock to the clock monitor phase frequency detect (PFD). The 10-MHz LPO fast clock is the compare clock for the clock detect PFD circuit and the source to limp clock on a clock fail. The ALTLMPCLOCK driven on the GIOB[0] pin is the compare clock for the clock detect PFD circuit and the source to limp clock on a clock fail. |
| 25 | RANGEDETCTRL | 0 1 | Range detection control. This bit's functionality is dependant on the state of the RANGEDETENASSEL bit (Bit 24) of the CLKTEST register. The clock monitor range detection circuitry (RANGEDETECTENABLE) is disabled. The clock monitor range detection circuitry (RANGEDETECTENABLE) is enabled. |
| 24 | RANGEDETENASSEL | 0 1 | Selects range detection enable. This bit resets asynchronously on power on reset. The range detect enable is generated by the hardware in the clock monitor wrapper. The range detect enable is controlled by the RANGEDETCTRL bit (Bit 25) of the CLKTEST register. |
| 23-20 | Reserved | 0 | Read returns 0. Writes have no effect. |
| 19-16 | CLK_TEST_EN | 5h Others | Clock test enable. This bit enables the clock going to the ECLK pin. Note: The ECLK pin must also be placed into Functional mode by setting the ECPCLKFUN bit to 1 in the SYSPC1 register. Clock going to ECLK pin is enabled. Clock going to ECLK pin is disabled. |
| 15-12 | Reserved | 0 | Read returns 0. Writes have no effect. |

| Bit | Field | Value | Description |
|-------|---------------|-------------------------------|--|
| 31-14 | Reserved | 0 | Read returns 0. Writes have no effect. |
| 13-12 | DFTWRITE | | DFT logic access. For F021: DFTWRITE[0] = 0 and DFTREAD[0] = 0 configured in stress mode DFTWRITE[1] = 0 and DFTREAD[1] = 0 configured in stress mode DFTWRITE[0] = 0 and DFTREAD[0] = 0 configured in fast mode DFTWRITE[1] = 1 and DFTREAD[1] = 1 configured in fast mode DFTWRITE[0] = 1 and DFTREAD[0] = 1 configured in slow mode DFTWRITE[1] = 0 and DFTREAD[1] = 0 configured in slow mode DFTWRITE[0] = 1 and DFTREAD[0] = 1 configured in screen mode DFTWRITE[1] = 1 and DFTREAD[1] = 1 configured in screen mode |
| 11-10 | Reserved | 0 | Read returns 0. Writes have no effect. |
| 9-8 | DFTREAD | | DFT logic access. For F021: DFTWRITE[0] = 0 and DFTREAD[0] = 0 configured in stress mode DFTWRITE[1] = 0 and DFTREAD[1] = 0 configured in stress mode DFTWRITE[0] = 0 and DFTREAD[0] = 0 configured in fast mode DFTWRITE[1] = 1 and DFTREAD[1] = 1 configured in fast mode DFTWRITE[0] = 1 and DFTREAD[0] = 1 configured in slow mode DFTWRITE[1] = 0 and DFTREAD[1] = 0 configured in slow mode DFTWRITE[0] = 1 and DFTREAD[0] = 1 configured in screen mode DFTWRITE[1] = 1 and DFTREAD[1] = 1 configured in screen mode |
| 7-4 | Reserved | 0 | Read returns 0. Writes have no effect. |
| 3-0 | TEST_MODE_KEY | 0-Fh (except Ah) Ah | Test mode key. This register is for internal TI use only. Register key disable. All bits in this register will maintain their default value and cannot be written. Register key enable. All the bits can be written to only when the key is enabled. On reset, these bits will be set to 5h. |

2.5.1.34 DFT Control Register 2 (DFTCTRLREG2)

This register is shown in [Figure 2-38](#) and described in [Table 2-52](#).

Figure 2-38. DFT Control Register 2 (DFTCTRLREG2) [offset = 94h]

LEGEND: R/W = Read/Write; R = Read only; WP = Write in privileged mode only; -n = value after reset

Table 2-52. DFT Control Register 2 (DFTCTRLREG2) Field Descriptions

| Bit | Field | Value | Description |
|------|---------------|---------------------------|--|
| 31-4 | IMPDPF[27:0] | 0 1 | DFT Implementation defined bits. IMPDPF[27:0] - Disabled IMPDPF[27:0] - Enabled |
| 3-0 | TEST_MODE_KEY | 0-Fh (except Ah) Ah | Test mode key. This register is for internal TI use only. Register key disable. All bits in this register will maintain their default value and cannot be written. Register key enable. All the bits can be written to only when the key is enabled. |

2.5.1.35 General Purpose Register (GPREG1)

This register is shown in [Figure 2-39](#) and described in [Table 2-53](#).

Figure 2-39. General Purpose Register (GPREG1) [offset = A0h]

| | | | | | | |
|----------------------------|----------|--------------------------|------------------------|----|----|----|
| 31 | 30 | 26 | 25 | 20 | 19 | 16 |
| EMIF_FUNC | Reserved | PLL1_FBSLIP_FILTER_COUNT | PLL1_FBSLIP_FILTER_KEY | | | |

| R/WP-FFFFh | | | | | | |

LEGEND: R/W = Read/Write; R = Read only; WP = Write in privileged mode only; -n = value after reset

Table 2-53. General Purpose Register (GPREG1) Field Descriptions

| Bit | Field | Value | Description |
|-------|--------------------------|------------------------------------|--|
| 31 | EMIF_FUNC | 0 | Enable EMIF functions to be output. EMIF_ADDR[0], EMIF_ADDR[1], EMIF_ADDR[6], EMIF_ADDR[7], EMIF_ADDR[8], EMIF_BA[1], EMIF_nCS[0], and EMIF_nCS[3] are multiplexed with N2HET2 signals. By default, these terminals are tri-stated and pulled down. Any application that requires the EMIF functionality must set the EMIF_FUNC bit. This allows these 8 EMIF module outputs to be driven on to the assigned balls. |
| 30-26 | Reserved | 0 | Read returns 0. Writes have no effect. |
| 25-20 | PLL1_FBSLIP_FILTER_COUNT | 0-3Fh 0 1h 2h : 3Fh | FBSLIP down counter programmed value. Configures the system response when a FBSLIP is indicated by the PLL macro. When PLL1_FBSLIP_FILTER_KEY is not 1010, the down counter counts from the programmed value on every LPO high frequency clock once PLL macro indicates FBSLIP. When the count reaches zero, if the synchronized FBSLIP signal is still high, an FBSLIP condition is indicated to the system module and is captured in the global status register. When the FBSLIP signal from the PLL macro is de-asserted before the count reaches 0, the counter is reloaded with the programmed value. Filtering is disabled. Every slip is recognized. Filtering is enabled. Every slip is recognized. Filtering is enabled. The slip must be at least 2 HF LPO cycles wide in order to be recognized as a slip. : Filtering is enabled. The slip must be at least 63 HF LPO cycles wide in order to be recognized as a slip. |
| 19-16 | PLL1_FBSLIP_FILTER_KEY | 5h Ah Fh All other values | Configures the system response when a FBSLIP is indicated by the PLL macro. The FBSLIP filter is bypassed and the FBSLIP indicated by the PLL macro is captured in the system module global status register. The FBSLIP filter is enabled and the one-stage synchronization circuit is used. The FBSLIP filter is enabled and the two-stage synchronization circuit is used. FBSLIP filtering is enabled. |

Table 2-53. General Purpose Register (GPREG1) Field Descriptions (continued)

| Bit | Field | Value | Description |
|------|----------------------------|----------|--|
| 15-0 | OUTPUT_BUFFER_LOW_EMI_MODE | | Control field for the low-EMI mode of output buffers for module/signals: bit[0] controls MiBSP1 bit[1] controls SPI2 bit[2] controls MiBSP3 bit[3] controls SPI4 bit[4] controls MiBSP5 bit[5] controls FlexRay bit[6] controls EMIF bit[7] Reserved bit[8] controls signal TMS bit[9] controls signal TDI bit[10] controls signal TDO bit[11] controls signal RTCK bit[12] controls signal TEST bit[13] controls signal nERROR bit[14] controls signal ADEVT bit[15] Reserved |
| | | 0 | Enable EMI mode for each connected output buffers. |
| | | 1h-FFFEh | Enable/Disable EMI mode for connected output buffers. |
| | | FFFFh | Disable EMI mode for each connected output buffer. |

2.5.1.36 Imprecise Fault Status Register (IMPFASTS)

The IMPFASTS register, shown in [Figure 2-40](#) and described in [Table 2-54](#), displays information about imprecise aborts that have occurred.

Figure 2-40. Imprecise Fault Status Register (IMPFASTS) [offset = A8h]

| | | | | | | | | | | | |
|----------|----|--|-------|------|----------|----------|--|--|--------|---|----|

LEGEND: R/W = Read/Write; R = Read only; C = Clear; -n = value after reset

Table 2-54. Imprecise Fault Status Register (IMPFASTS) Field Descriptions

| Bit | Field | Value | Description |
|-------|----------|--------|---|
| 31-24 | Reserved | 0 | Read returns 0. Writes have no effect. |
| 23-16 | MASTERID | 0-FFh | Master ID. This register indicates which master is responsible for the imprecise abort. The master ID value depends on device implementation- see Table 2-2 for MASTERID values for each bus master. Notes: <ul style="list-style-type: none"> These bits are only updated when an imprecise abort occurs These bits are cleared to 0 only on power-up reset. The value of these bits remains unchanged after all other resets. |
| 15-11 | Reserved | 0 | Read returns 0. Writes have no effect. |
| 10 | EMIFA | 0 1 | EMIF imprecise abort. This register indicates the imprecise abort was generated writing into the EMIF. Notes: <ul style="list-style-type: none"> This bit is only updated when an imprecise abort occurs This bit is cleared to 0 only on power-up reset. The value of this register remains unchanged after all other resets. 0 EMIF did not generate the last imprecise abort. 1 EMIF was written with an illegal address and generated an imprecise abort. |
| 9 | NCBA | 0 1 | Non-cacheable, bufferable abort (NCBA). This register indicates the imprecise abort was generated by a non-cacheable, bufferable write or shared device write through the write buffer of the CPU. Notes: <ul style="list-style-type: none"> This bit is only updated when an imprecise abort generated by a non-cacheable, bufferable write or shared device write occurs. This bit is cleared to 0 only on power-up reset. The value of this register remains unchanged after all other resets. 0 A NCBA is not responsible for the last imprecise abort. 1 A NCBA was written with an illegal address and generated an imprecise abort. |
| 8 | VBUSA | 0 1 | VBUS abort. This register indicates the imprecise abort was generated when writing into the peripheral frame. Notes: <ul style="list-style-type: none"> This bit is only updated when an imprecise abort is generated when writing into the peripheral frame This bit is cleared to 0 only on power-up reset. The value of this register remains unchanged after all other resets. 0 The peripheral frame did not generate the last imprecise abort. 1 The peripheral frame was written with an illegal address and generated an imprecise abort. |
| 7-1 | Reserved | 0 | Read returns 0. Writes have no effect. |

Table 2-54. Imprecise Fault Status Register (IMPFASTS) Field Descriptions (continued)

| Bit | Field | Value | Description |
|-----|-------|-------|---|
| 0 | ATYPE | | <p>Abort type. This bit indicates to the CPU whether the last abort was an imprecise abort or a precise abort.</p> <p>Notes:</p> <ul style="list-style-type: none"> This bit is updated after each abort is generated to the CPU. This bit is cleared on CPU read. This bit is cleared to 0 only on power-up reset. The value of this bit remains unchanged after all other resets <p>0 The last abort generated was a precise abort. MASTERID, VBUSA, NCBA, EMIFA and IMPFTADD were not updated.</p> <p>1 The last abort generated was an imprecise abort. MASTERID, VBUSA, NCBA, EMIFA and IMPFTADD were updated.</p> <p>Note: Once ATYPE is set, the IMPFAWADD and IMPFASTS bits are not updated by subsequent ABORT signals.</p> |

NOTE: The DMA and the peripheral master port will also generate an imprecise abort to the CPU when writing to the peripheral region or to the EMIF region. This will be indicated in the Master ID field of this register.

2.5.1.37 Imprecise Fault Address Register (IMPFTADD)

This IMPFTADD register, shown in [Figure 2-41](#) and described in [Table 2-55](#), shows the address at which an imprecise abort occurred.

Figure 2-41. Imprecise Fault Write Address Register (IMPFTADD) [offset = ACh]

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 2-55. Imprecise Fault Write Address Register (IMPFTADD) Field Descriptions

| Bit | Field | Value | Description |
|------|----------|---------------|--|
| 31-0 | IMPFTADD | 0- FFFF FFFFh | <p>These bits contain the fault address when an imprecise abort occurs.</p> <p>Note: These bits are only updated when an imprecise abort occurs.</p> <p>Note: These bits are cleared to 0 only on power-up reset. The value of this register remains unchanged after all other resets.</p> |

2.5.1.38 System Software Interrupt Request 1 Register (SSIR1)

The SSIR1 register, shown in [Figure 2-42](#) and described in [Table 2-56](#), is used for software interrupt generation.

Figure 2-42. System Software Interrupt Request 1 Register (SSIR1) [offset = B0h]

| | | | | | | | | | | | | | | | | | |
|-------|----------|--|--|--|--|--|--|--|-------|---|---------|--|--|--|--|--|----|
| 31 | Reserved | | | | | | | | | | | | | | | | 16 |

| 15 | SSKEY1 | | | | | | | | 8 | 7 | SSDATA1 | | | | | | 0 |
| R/W-0 | | | | | | | | | R/W-0 | | | | | | | | |

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 2-56. System Software Interrupt Request 1 Register (SSIR1) Field Descriptions

| Bit | Field | Value | Description |
|-------|----------|-------|--|
| 31-16 | Reserved | 0 | Read returns 0. Writes have no effect. |
| 15-8 | SSKEY1 | 0-FFh | System software interrupt request key. A 075h written to these bits initiates IRQ/FIQ interrupts. Data in this field is always read as 0. The SSKEY1 field can be written into only if the write data matches the key (75h). The SSDATA1 field can only be written into if the write data into this field, the SSKEY1 field, matches the key (75h). |
| 7-0 | SSDATA1 | 0-FFh | System software interrupt data. These bits contain user read/write register bits. They may be used by the application software as different entry points for the interrupt routine. The SSDATA1 field cannot be written into unless the write data into the SSKEY1 field matches the key (75h); therefore, byte writes cannot be performed on the SSDATA1 field. |

NOTE: This register is mirrored at offset FCh for compatibility reasons.

2.5.1.39 System Software Interrupt Request 2 Register (SSIR2)

The SSIR2 register, shown in [Figure 2-43](#) and described in [Table 2-57](#), is used for software interrupt generation.

Figure 2-43. System Software Interrupt Request 2 Register (SSIR2) [offset = B4h]

| | | | | | | | | | | | | | | | | | |

Table 2-57. System Software Interrupt Request 2 Register (SSIR2) Field Descriptions

| Bit | Field | Value | Description |
|-------|----------|-------|--|
| 31-16 | Reserved | 0 | Read returns 0. Writes have no effect. |
| 15-8 | SSKEY2 | 0-FFh | System software interrupt2 request key. A 84h written to these bits initiates IRQ/FIQ interrupts. Data in this field is always read as 0. The SSKEY2 field can be written into only if the write data matches the key (84h). The SSDATA2 field can only be written into if the write data into this field, the SSKEY2 field, matches the key (84h). |
| 7-0 | SSDATA2 | 0-FFh | System software interrupt data. These bits contain user read/write register bits. They may be used by the application software as different entry points for the interrupt routine. The SSDATA2 field cannot be written into unless the write data into the SSKEY2 field matches the key (84h); therefore, byte writes cannot be performed on the SSDATA2 field. |

2.5.1.40 System Software Interrupt Request 3 Register (SSIR3)

The SSIR3 register, shown in [Figure 2-44](#) and described in [Table 2-58](#), is used for software interrupt generation.

Figure 2-44. System Software Interrupt Request 3 Register (SSIR3) [offset = B8h]

| | | | | | | | | | | | | | | | | | |

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 2-58. System Software Interrupt Request 3 Register (SSIR3) Field Descriptions

| Bit | Field | Value | Description |
|-------|----------|-------|--|
| 31-16 | Reserved | 0 | Read returns 0. Writes have no effect. |
| 15-8 | SSKEY3 | 0-FFh | System software interrupt request key. A 93h written to these bits initiates IRQ/FIQ interrupts. Data in this field is always read as 0. The SSKEY3 field can be written into only if the write data matches the key (93h). The SSDATA3 field can only be written into if the write data into this field, the SSKEY3 field, matches the key (93h). |
| 7-0 | SSDATA3 | 0-FFh | System software interrupt data. These bits contain user read/write register bits. They may be used by the application software as different entry points for the interrupt routine. The SSDATA3 field cannot be written into unless the write data into the SSKEY3 field matches the key (93h); therefore, byte writes cannot be performed on the SSDATA3 field. |

2.5.1.41 System Software Interrupt Request 4 Register (SSIR4)

The SSIR4 register, shown in [Figure 2-45](#) and described in [Table 2-59](#), is used for software interrupt generation.

Figure 2-45. System Software Interrupt Request 4 Register (SSIR4) [offset = BCh]

| | | | | | | | | | | | | | | | | | |
|-------|----------|--|--|--|--|--|--|--|-------|---|---------|--|--|--|--|--|----|

Table 2-59. System Software Interrupt Request 4 Register (SSIR4) Field Descriptions

| Bit | Field | Value | Description |
|-------|----------|-------|--|
| 31-16 | Reserved | 0 | Read returns 0. Writes have no effect. |
| 15-8 | SSKEY4 | 0-FFh | System software interrupt2 request key. A A2h written to these bits initiates IRQ/FIQ interrupts. Data in this field is always read as 0. The SSKEY4 field can be written into only if the write data matches the key (A2h). The SSDATA4 field can only be written into if the write data into this field, the SSKEY4 field, matches the key (A2h). |
| 7-0 | SSDATA4 | 0-FFh | System software interrupt data. These bits contain user read/write register bits. They may be used by the application software as different entry points for the interrupt routine. The SSDATA4 field cannot be written into unless the write data into the SSKEY4 field matches the key (A2h); therefore, byte writes cannot be performed on the SSDATA4 field. |

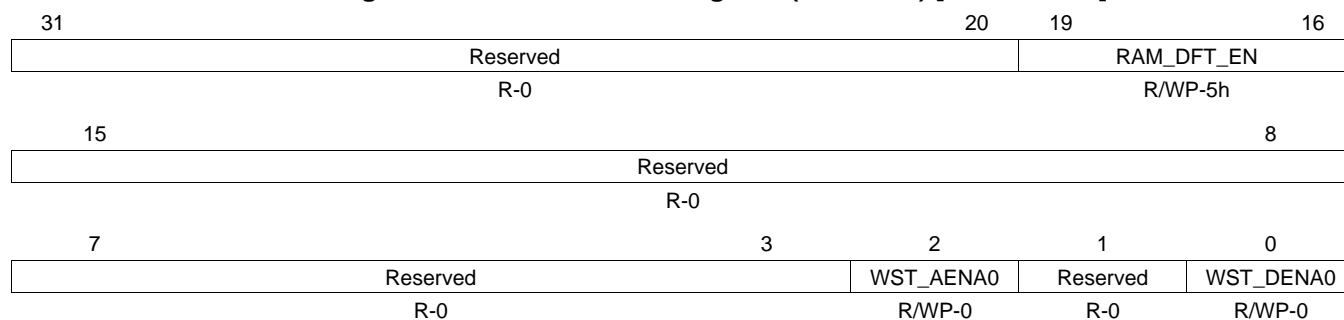

2.5.1.42 RAM Control Register (RAMGCR)

The RAMGCR register, shown in Figure 2-46 and described in Table 2-60, is used to configure eSRAM data and address wait states.

NOTE: The RAM_DFT_EN bits are for TI internal use only.

The contents of the RAM_DFT_EN field should not be changed.

Figure 2-46. RAM Control Register (RAMGCR) [offset = C0h]

LEGEND: R/W = Read/Write; R = Read only; WP = Write in privileged mode only; -n = value after reset

Table 2-60. RAM Control Register (RAMGCR) Field Descriptions

| Bit | Field | Value | Description |
|-------|------------|--------------|--|
| 31-20 | Reserved | 0 | Read returns 0. Writes have no effect. |
| 19-16 | RAM_DFT_EN | Ah Others | Functional mode RAM DFT (Design For Test) port enable key. Note: For TI internal use only. RAM DFT port is enabled. RAM DFT port is disabled. Note: It is recommended that a value of 5h be used to disable the RAM DFT port. This value will give maximum protection from a bit flip inducing event that would inadvertently enable the controller. |
| 15-3 | Reserved | 0 | Read returns 0. Writes have no effect. |
| 2 | WST_AENAO | 0 1 | eSRAM data phase wait state enable bit. The default address setup time for eSRAM0 is used. The eSRAM address setup time is increased by one HCLK cycle. |
| 1 | Reserved | 0 | Read returns 0. Writes have no effect. |
| 0 | WST_DENAO | 0 1 | eSRAM data phase wait state enable bit. There are no wait states for eSRAM during the data phase. The eSRAM data phase setup time is increased by one HCLK cycle. |

2.5.1.43 Bus Matrix Module Control Register 1 (BMMCR1)

The BMMCR1 register, shown in [Figure 2-47](#) and described in [Table 2-61](#), allows RAM and Program (Flash) memory addresses to be swapped.

Figure 2-47. Bus Matrix Module Control Register 1 (BMMCR) [offset = C4h]

| | | | | | | | | | | | | | | |
|----------|--|--|--|--|--|--|--|--|--|--|---------|---|----|---|

| 15 | | | | | | | | | | | 4 | 3 | | 0 |
| Reserved | | | | | | | | | | | MEMSW | | | |
| R-0 | | | | | | | | | | | R/WP-Ah | | | |

LEGEND: R/W = Read/Write; R = Read only; WP = Write in privileged mode only; -n = value after reset

Table 2-61. Bus Matrix Module Control Register 1 (BMMCR) Field Descriptions

| Bit | Field | Value | Description |
|------|----------|--------|--|
| 31-4 | Reserved | 0 | Read returns 0. Writes have no effect. |
| 3-0 | MEMSW | | Memory swap key. Note: A CPU reset must be issued after the memory swap key has been changed for the memory swap to occur. A CPU reset can be initiated by changing the state of the CPU RESET bit in the CPURSTCR register. |
| | | 5h | Swapped memory-map: eSRAM starts at address 0. Program memory (Flash) starts at address 800 0000h. |
| | | Ah | Default memory-map: Program memory (Flash) starts at address 0. eSRAM starts at address 800 0000h. |
| | | Others | The device memory-map is unchanged. |

2.5.1.44 CPU Reset Control Register (CPURSTCR)

The CPURSTCR register shown in [Figure 2-48](#) and described in [Table 2-62](#), allows the memory protection mode to be configured. It also allows a reset to the Cortex R4 CPU to be generated.

Figure 2-48. CPU Reset Control Register (CPURSTCR) [offset = CCh]

Table 2-62. CPU Reset Control Register (CPURSTGCR) Field Descriptions

| Bit | Field | Value | Description |
|------|-----------|-------|---|
| 31-1 | Reserved | 0 | Read returns 0. Writes have no effect. |
| 0 | CPU RESET | | CPU Reset. Only the CPU is reset whenever this bit is toggled. There is no system reset. |

2.5.1.45 Clock Control Register (CLKCNTL)

The CLKCNTL register, shown in [Figure 2-49](#) and described in [Table 2-63](#), controls peripheral reset and the peripheral clock divide ratios.

NOTE: VCLK and VCLK2 clock ratio restrictions.

VCLK2 must always be greater than or equal to VCLK. In addition, the VCLK and VCLK2 clock ratios must not be changed simultaneously. The application must configure the VCLK2 ratio, read back the contents of the CLKCNTL register, and then configure the VCLK ratio.

Figure 2-49. Clock Control Register (CLKCNTL) [offset = D0h]

| | | | | | | | |

Table 2-63. Clock Control Register (CLKCNTL) Field Descriptions

| Bit | Field | Value | Description |
|-------|----------|--------------|---|
| 31-28 | Reserved | 0 | Read returns 0. Writes have no effect. |
| 27-24 | VCLK2R | 0 : Fh | VBUS clock2 ratio. The VCLK2 speed is HCLK divided by 1. : The VCLK2 speed is HCLK divided by 16. |
| 23-20 | Reserved | 0 | Read returns 0. Writes have no effect. |
| 19-16 | VCLKR | 0 : Fh | VBUS clock ratio. The VCLK speed is HCLK divided by 1. : The VCLK speed is HCLK divided by 16. |
| 15-9 | Reserved | 0 | Read returns 0. Writes have no effect. |
| 8 | PENA | 0 1 | Peripheral enable bit. The application must set this bit before accessing any peripheral The global peripheral/peripheral memory frames are in reset. All peripheral/peripheral memory frames are out of reset. |
| 7-0 | Reserved | 0 | Read returns 0. Writes have no effect. |

2.5.1.46 ECP Control Register (ECPCNTL)

The ECP register, shown in Figure 2-50 and described in Table 2-64, configures the ECLK pin in functional mode.

NOTE: ECLK Functional mode configuration.

The ECLK pin must be placed into Functional mode by setting the ECPCLKFUN bit to 1 in the SYSPC1 register before a clock source will be visible on the ECLK pin.

Figure 2-50. ECP Control Register (ECPCNTL) [offset = D4h]

| | | | | | | | |

| 31 | 25 | 24 | 23 | 22 | 18 | 17 | 16 |
| Reserved | | | | | Reserved | | ECPINSEL |
| R-0 | | | | | R-0 | | R/W-0 |
| 15 | ECPDIV | | | | | | 0 |
| R/W-0 | | | | | | | |

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 2-64. ECP Control Register (ECPCNTL) Field Descriptions

| Bit | Field | Value | Description |
|-------|----------|---------------------|--|
| 31-25 | Reserved | 0 | Read returns 0. Writes have no effect. |
| 24 | ECPSEL | 0 1 | This bit allows the selection between VCLK and OSCIN as the clock source for ECLK. Note: Other ECLK clock sources are available for debug purposes by configuring the CLKTEST register. VCLK is selected as the ECP clock source. OSCIN is selected as the ECP clock source. |
| 23 | ECPCOS | 0 1 | ECP continue on suspend. Note: Suspend mode is entered while performing certain JTAG debugging operations. ECLK output is disabled in suspend mode. ECLK output will be shut off and will not be seen on the I/O pin of the device. ECLK output is not disabled in suspend mode. ECLK output will not be shut off and will be seen on the I/O pin of the device. |
| 22-18 | Reserved | 0 | Read returns 0. Writes have no effect. |
| 17-6 | ECPINSEL | 0 1h 2h 3h | Select ECP input clock source. Tied Low HCLK External clock Tied Low |
| 15-0 | ECPDIV | 0-FFFFh | ECP divider value. The value of ECPDIV bits determine the external clock (ECP clock) frequency as a ratio of VBUS clock or OSCIN as shown in the formula: $ECLK = \frac{VCLK \text{ or } OSCIN}{(ECPDIV + 1)}$ |

(1)

2.5.1.47 DEV Parity Control Register 1 (DEVCR1)

This register is shown in [Figure 2-51](#) and described in [Table 2-65](#).

Figure 2-51. DEV Parity Control Register 1 (DEVCR1) [offset = DCh]

| | | | | | | | | | | | | | | | | |

LEGEND: R/W = Read/Write; R = Read only; WP = Write in privileged mode only; -n = value after reset

Table 2-65. DEV Parity Control Register 1 (DEVCR1) Field Descriptions

| Bit | Field | Value | Description |
|------|-----------|-------|---|
| 31-4 | Reserved | 0 | Read returns 0. Writes have no effect. |
| 3-0 | DEVPARSEL | | Device parity select bit key. Note: After an odd (DEVPARSEL = 5h) or even (DEVPARSEL = Ah) scheme is programmed into the DEVPARSEL register, any one bit change can be detected and will retain its programmed scheme. More than one bit changes in DEVPARSEL will cause a default to odd parity scheme. |
| | | 5h | The device parity is even. |
| | | Ah | The device parity is odd. |

2.5.1.48 System Exception Control Register (SYSECR)

The SYSECR register, shown in [Figure 2-52](#) and described in [Table 2-66](#), is used to generate a software reset.

Figure 2-52. System Exception Control Register (SYSECR) [offset = E0h]

LEGEND: R/W = Read/Write; R = Read only; WP = Write in privileged mode only; -n = value after reset

Table 2-66. System Exception Control Register (SYSECR) Field Descriptions

| Bit | Field | Value | Description |
|-------|------------|--------|--|
| 31-16 | Reserved | 0 | Read returns 0. Writes have no effect. |
| 15-14 | RESET[1-0] | | Software reset bits. Setting RESET1 or clearing RESET0 causes a system software reset. |
| | | 1h | No reset will occur. |
| | | 1x, x0 | A global system reset will occur. |
| 13-0 | Reserved | 0 | Read returns 0. Writes have no effect. |

2.5.1.49 System Exception Status Register (SYSESR)

The SYSESR register, shown in Figure 2-53 and described in Table 2-67, shows the source for different resets encountered. Previous reset source status bits are not automatically cleared if new resets occur. After reading this register, the software should clear any flags that are set so that the source of future resets can be determined. Any bit in this register can be cleared by writing a '1' to the bit.

LEGEND: R/W = Read/Write; R = Read only; C = Clear; X = value unchanged after reset; X* = 0 after PORST but unchanged after other resets; -n = value after reset

Table 2-67. System Exception Status Register (SYSESR) Field Descriptions

| Bit | Field | Value | Description |
|-------|----------|--------|---|
| 31-16 | Reserved | 0 | Read returns 0. Writes have no effect. |
| 15 | PORST | 0 1 | Power-on reset. This bit is set when a power-on reset occurs, either internally asserted by the VMON or externally asserted by the nPORRST pin. No power-on reset has occurred since this bit was last cleared. A reset was caused by a power-on reset. (This bit should be cleared after being read so that subsequent resets can be properly identified as not being power-on resets.) |
| 14 | OSCRST | 0 1 | Reset caused by an oscillator failure or PLL cycle slip. This bit is set when a reset is caused by an oscillator failure or PLL slip. Note: The action taken when an oscillator failure or PLL slip is detected must be configured in the PLLCTL1 register. No reset has occurred due to an oscillator failure or a PLL cycle slip. A reset was caused by an oscillator failure or a PLL cycle slip. |
| 13 | WDRST | 0 1 | Watchdog reset flag. This bit is set when the last reset was caused by the digital windowed watchdog. During debugging, the ICEPICK logic implemented on the microcontroller also allows a system reset to be generated via the debug logic. This reset is also indicated on the WDRST bit of the SYSESR. This flag can also be set via a reset driven by ICEPICK. No reset has occurred because of the DWWD. A reset was caused by the DWWD. |
| 12-6 | Reserved | 0 | Read returns 0. Writes have no effect. |
| 5 | CPURST | 0 1 | CPU reset flag. This bit is set when the CPU is reset. Note: A CPU reset can be initiated by the CPU self-test controller (LBIST) or by changing the memory protection (MMU/MPU) configuration in CPURSTCR register. No CPU reset has occurred. A CPU reset occurred. |
| 4 | SWRST | 0 1 | Software reset flag. This bit is set when a software system reset has occurred. Note: A software system reset can be initiated by writing to the RESET bits in the SYSECR register. No software reset has occurred. A software reset occurred. |

Table 2-67. System Exception Status Register (SYSESR) Field Descriptions (continued)

| Bit | Field | Value | Description |
|-----|----------|--------|---|
| 3 | EXTRST | 0 1 | External reset flag. This bit is set when a reset is caused by the external reset pin nRST or by any reset that also asserts the nRST pin (PORST, OSCRST, WDRST and SWRST). The external reset pin has not asserted a reset. A reset has been caused by the external reset pin. |
| 2-1 | Reserved | 0 | Read returns 0. Writes have no effect. |
| 0 | MPMODE | 0 1 | This indicates the current memory protection unit (MPU) mode. MPU is disabled. MPU is enabled. |

2.5.1.50 System Test Abort Status Register (SYSTASR)

This register is shown in [Figure 2-54](#) and described in [Table 2-68](#).

Figure 2-54. System Test Abort Status Register (SYSTASR) [offset = E8h]

| R-0 | | R/WPC-X/0 |

LEGEND: R/W = Read/Write; R = Read only; WP = Write in privileged mode only; C = Clear; -X = Value unchanged after reset; -n = value after reset

Table 2-68. System Test Abort Status Register (SYSTASR) Field Descriptions

| Bit | Field | Value | Description |
|------|-------------|--|--|
| 31-5 | Reserved | 0 | Read returns 0. Writes have no effect. |
| 4-0 | EFUSE_Abort | 0 1h 2h 3h 4h Others 1Fh | Test Abort status flag. These bits are set when test abort occurred: <i>Read:</i> The last operation (if any) completed successfully. This is also the value that the error/status register is set to after reset. <i>Read:</i> Controller times out because there is no last row sent from the FuseROM. <i>Read:</i> The autoloading machine was started, either through the SYS_INITZ signal from the system or the JTAG data register. In either case, the autoloading machine did not find enough FuseROM data to fill the scan chain. <i>Read:</i> The autoloading machine was started, either through the SYS_INITZ signal from the system or the JTAG data register. In either case, the autoloading machine starts the scan chain with a signature it expects to see after the scan chain is full. The autoloading machine was able to fill the scan chain, but the wrong signature was returned. <i>Read:</i> The autoloading machine was started, either through the SYS_INITZ signal from the system or the JTAG data register. In either case, the autoloading machine was not able or not allowed to complete its operation. <i>Read:</i> Reserved. <i>Write:</i> These bits are cleared to 0. |

2.5.1.51 Global Status Register (GLBSTAT)

The GLBSTAT register, shown in [Figure 2-55](#) and described in [Table 2-69](#), indicates the FMzPLL (PLL1) slip status and the oscillator fail status.

NOTE: PLL and OSC fail behavior

The device behavior after a PLL slip or an oscillator failure is configured in the PLLCTL1 register.

Figure 2-55. Global Status Register (GLBSTAT) [offset = ECh]

LEGEND: R/W = Read/Write; R = Read only; W1C = Write 1 to Clear; -n = value after reset

Table 2-69. Global Status Register (GLBSTAT) Field Descriptions

| Bit | Field | Value | Description |
|-------|----------|-------|---|
| 31-10 | Reserved | 0 | Read returns 0. Writes have no effect. |
| 9 | FBSLIP | 0 | PLL over cycle slip detection. (cleared by nPORRST, maintains its previous value for all other resets) <i>Read:</i> No PLL over cycle slip has been detected. <i>Write:</i> The bit is unchanged. |
| | | 1 | <i>Read:</i> A PLL over cycle slip has been detected. <i>Write:</i> The bit is cleared to 0. |
| 8 | RFSLIP | 0 | PLL under cycle slip detection. (cleared by nPORRST, maintains its previous value for all other resets) <i>Read:</i> No PLL under cycle slip has been detected. <i>Write:</i> The bit is unchanged. |
| | | 1 | <i>Read:</i> A PLL under cycle slip has been detected. <i>Write:</i> The bit is cleared to 0. |
| 7-1 | Reserved | 0 | Read returns 0. Writes have no effect. |
| 0 | OSCFAIL | 0 | Oscillator fail flag bit. (cleared by nPORRST, maintains its previous value for all other resets) <i>Read:</i> No oscillator failure has been detected. <i>Write:</i> The bit is unchanged. |
| | | 1 | <i>Read:</i> An oscillator failure has been detected. <i>Write:</i> The bit is cleared to 0. |

2.5.1.52 Device Identification Register (DEVID)

The DEVID is a read-only register. It contains device-specific information that is hard-coded during device manufacture. For the initial silicon version, the device identification code value is 802A AD05h. This register is shown in [Figure 2-56](#) and described in [Table 2-70](#).

Figure 2-56. Device Identification Register (DEVID) [offset = F0h]

| | | | | | | | | | | | | | |

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset; -K = Constant value

Table 2-70. Device Identification Register (DEVID) Field Descriptions

| Bit | Field | Value | Description |
|-------|----------------------|--|--|
| 31 | CP15 | 0 1 | CP15 CPU. This bit indicates whether the CPU has a coprocessor 15 (CP15). The CPU has no CP15 present. The CPU has a CP15 present. The CPU ID can be read using the CP15 C0,C0,0 register. |
| 30-17 | UNIQUE ID | 0-3FFFh | Device ID. The device ID is unique by device configuration. |
| 16-13 | TECH | 0 1h 2h 3h 4h 5h 6h-Fh | These bits define the process technology by which the device was manufactured. Device manufactured in the C05 process technology. Device manufactured in the F05 process technology. Device manufactured in the C035 process technology. Device manufactured in the F035 process technology. Device manufactured in the C021 process technology. Device manufactured in the F021 process technology. Reserved |
| 12 | I/O VOLTAGE | 0 1 | Input/output voltage. This bit defines the I/O voltage of the device. The I/O voltage is 3.3 V. The I/O voltage is 5 V. |
| 11 | PERIPHERAL PARITY | 0 1 | Peripheral parity. This bit indicates whether or not peripheral memory parity is present. The peripheral memories have no parity. The peripheral memories have parity. |
| 10-9 | FLASH ECC | 0 1h 2h 3h | These bits indicate which parity is present for the program memory. No memory protection is present. The program memory (Flash) has single bit parity. The program memory (Flash) has ECC. This combination is reserved. |
| 8 | RAM ECC | 0 1 | RAM ECC. This bit indicates whether or not RAM memory ECC is present. The RAM memories do not have ECC. The RAM memories have ECC. |
| 7-3 | VERSION | 0-1Fh | Version. These bits provide the revision of the device. |
| 2-0 | PLATFORM ID | 5h | The device is part of the TMS570 family. The TMS570 ID is always 5h. |

2.5.1.53 Software Interrupt Vector Register (SSIVEC)

The SSIVEC register, shown in [Figure 2-57](#) and described in [Table 2-71](#), contains information about software interrupts.

Figure 2-57. Software Interrupt Vector Register (SSIVEC) [offset = F4h]

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

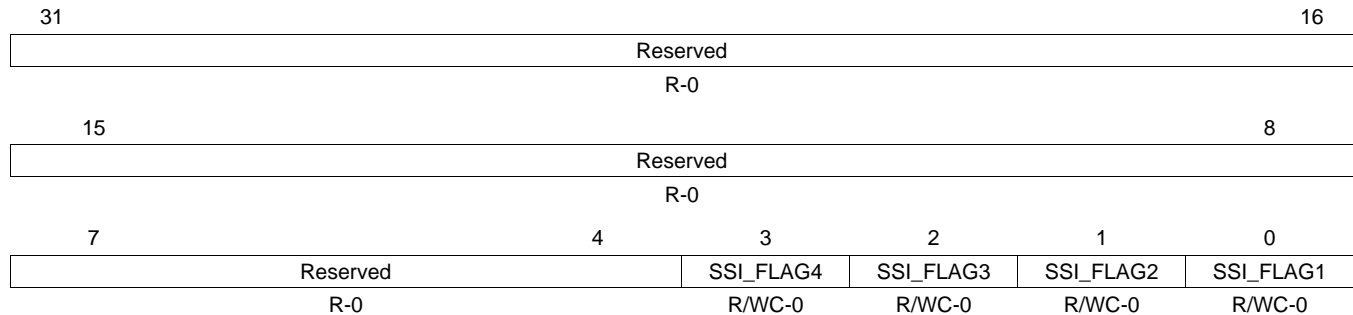

Table 2-71. Software Interrupt Vector Register (SSIVEC) Field Descriptions

| Bit | Field | Value | Description |
|-------|----------|---|---|
| 31-16 | Reserved | 0 | Read returns 0. Writes have no effect. |
| 15-8 | SSIDATA | 0-FFh | System software interrupt data key. These bits contain the data key value of the source for the system software interrupt, which is indicated by the vector in the SSIVEC[7-0] field. |
| 7-0 | SSIVECT | <div> <div></div> <div>0</div> <div>1h</div> <div>2h</div> <div>3h</div> <div>4h</div> <div>5h-FFh</div> </div> | <div> <div>These bits contain the source for the system software interrupt.</div> <div> Note: A read from the SSIVECT bits clears the corresponding SSI_FLAG[4-1] bit in the SSIF register, corresponding to the source vector of the system software interrupt. </div> <div> Note: The SSIR[4-1] interrupt has the following priority order: SSIR1 has the highest priority. SSIR4 has the lowest priority. </div> <div>No software interrupt is pending.</div> <div>A software interrupt has been generated by writing the correct key value to The SSIR1 register.</div> <div>A software interrupt has been generated by writing the correct key value to The SSIR2 register.</div> <div>A software interrupt has been generated by writing the correct key value to The SSIR3 register.</div> <div>A software interrupt has been generated by writing the correct key value to The SSIR4 register.</div> <div>Reserved</div> </div> |

2.5.1.54 System Software Interrupt Flag Register (SSIF)

The SSIF register, shown in [Figure 2-58](#) and described in [Table 2-72](#), contains software interrupt flag status information.

Figure 2-58. System Software Interrupt Flag Register (SSIF) [offset = F8h]

LEGEND: R/W = Read/Write; R = Read only; C = Clear; -n = value after reset

Table 2-72. System Software Interrupt Flag Register (SSIF) Field Descriptions

| Bit | Field | Value | Description |
|------|---------------|-------|--|
| 31-4 | Reserved | 0 | Read returns 0. Writes have no effect. |
| 3-0 | SSI_FLAG[4-1] | | System software interrupt flag[4-1]. This flag is set when the correct SSKEY is written to the SSIR register[4-1]. Note: A read from the SSIVEC register clears the corresponding SSI_FLAG [4-1] bit in the SSIF, corresponding to the source vector of the system software interrupt. |
| | | 0 | <i>Read:</i> No IRQ/FIQ interrupt was generated since the bit was last cleared. <i>Write:</i> The bit is unchanged. |
| | | 1 | <i>Read:</i> An IRQ/FIQ interrupt was generated. <i>Write:</i> The bit is cleared to 0. |

2.5.2 Secondary System Control Registers (SYS2)

[Table 2-73](#) lists the secondary frame of system registers. The start address of the second system module frame is FFFF E100h. The registers support 32-, 16-, and 8-bit writes. The offset is relative to the system module frame start address.

Table 2-73. Secondary System Control Registers

| Offset | Acronym | Register Description | Section |
|---------|-------------|--|----------------------------------|
| 00h | PLLCTL3 | PLL Control Register 3 | Section 2.5.2.1 |

Field Descriptions**

| Bit | Field | Value | Description |
|-------|------------------|--|--|
| 31-27 | Reserved | 0 | Read returns 0. Writes have no effect. |
| 26-24 | VCLKA4R | 0 : 7h | Clock divider for the VCLKA4 source. Output will be present on VCLKA4_DIVR. VCLKA4 domain will be enabled by writing to the CDDIS register and VCLKA4_DIV_CDDIS bit. It can be inferred that VCLKA4_DIV clock is disabled when VCLKA4 clock is disabled. The ratio is VCLKA4 divided by 1. : The ratio is VCLKA4 divided by 8. |
| 23-21 | Reserved | 0 | Read returns 0. Writes have no effect. |
| 20 | VCLKA4_DIV_CDDIS | 0 1 | Disable the VCLKA4 divider output. VCLKA4 domain will be enabled by writing to the CDDIS register. Enable the prescaled VCLKA4 clock on VCLKA4_DIVR. Disable the prescaled VCLKA4 clock on VCLKA4_DIVR. |
| 19-16 | VCLKA4S | 0 1h 2h 3h 4h 5h 6h 7h 8h-Fh | Peripheral asynchronous clock4 source. Clock source0 is the source for peripheral asynchronous clock4. Clock source1 is the source for peripheral asynchronous clock4. Clock source2 is the source for peripheral asynchronous clock4. Clock source3 is the source for peripheral asynchronous clock4. Clock source4 is the source for peripheral asynchronous clock4. Clock source5 is the source for peripheral asynchronous clock4. Clock source6 is the source for peripheral asynchronous clock4. Clock source7 is the source for peripheral asynchronous clock4. VCLK is the source for peripheral asynchronous clock4. |
| 15-0 | Reserved | 0 | Reserved |

NOTE: Nonimplemented clock sources should not be enabled or used. A list of the available clock sources is shown in [Table 2-9](#).

2.5.2.5 Clock Slip Register (CLKSLIP)

This register is shown in [Figure 2-63](#) and described in [Table 2-78](#).

Figure 2-63. Clock Slip Register (CLKSLIP) [offset = 70h]

LEGEND: R/W = Read/Write; R = Read only; WP = Write in privileged mode only; -n = value after reset

Table 2-78. Clock Slip Register (CLKSLIP) Field Descriptions

| Bit | Field | Value | Description |
|-------|------------------------|---------------------------|---|
| 31-14 | Reserved | 0 | Read returns 0. Writes have no effect. |
| 13-8 | PLL1_SLIP_FILTER_COUNT | 0 1h 2h : 3Fh | Configure the count for the filtered PLL slip. Count is on 10M clock. On reset, counter value is zero. Counter must be programmed to non-zero value and enabled for the filtering to be enabled. Filtering is disabled. Every slip is recognized. Filtering is enabled. Every slip is recognized. Filtering is enabled. The slip must be at least 2 HF LPO cycles wide in order to be recognized as a slip. : Filtering is enabled. The SLIP must be at least 63 HF LPO cycles wide in order to be recognized as a slip. |
| 7-4 | Reserved | 0 | Read returns 0. Writes have no effect. |
| 3-0 | PLL1_SLIP_FILTER_KEY | 5h Fh Others | Enable the PLL slip filtering. On reset, the PLL filter is disabled and normal PLL slip passes through. This is an unsupported value. Avoid writing this value to this field. Enable of filtered PLL slip. Recommended to program Ah in these bit fields. Enable of PLL slip occurs when the KEY is programmed and a non-zero value is present in the COUNT field. |

2.5.2.6 EFUSE Controller Control Register (EFC_CTLREG)

This register is shown in [Figure 2-64](#) and described in [Table 2-79](#).

Figure 2-64. EFUSE Controller Control Register (EFC_CTLREG) [offset = ECh]

2.5.3 Peripheral Central Resource (PCR) Control Registers

This section describes the Peripheral Central Resource (PCR) control registers. The start address of the PCR register frame is FFFF E000h. [Table 2-84](#) summarizes the registers in the PCR, which are used to configure protection to the peripherals in PCS and PS regions. Not all chip selects exist on this device.

Table 2-84. Peripheral Central Resource Control Registers

| Offset | Acronym | Register Description | Section |

| Bit | Field | Value | Description |
|------|-------------------|-------|--|
| 31-0 | PCS[63-32]PROTCLR | 0 | Peripheral memory frame protection clear. <i>Read:</i> The peripheral memory frame can be written to and read from in both user and privileged modes. <i>Write:</i> The bit is unchanged. |
| | | 1 | <i>Read:</i> The peripheral memory frame can be written to only in privileged mode, but it can be read in both user and privileged modes. <i>Write:</i> The corresponding bit in PMPROTSET1 and PMPROTCLR1 registers is cleared to 0. |

2.5.3.5 Peripheral Protection Set Register 0 (PPROTSET0)

There is one bit for each quadrant for PS0 to PS7.

The following are the ways in which quadrants are used within a PS frame-

(a) The slave uses all the four quadrants.

Only the bit corresponding to the quadrant 0 of PSn is implemented. It protects the whole 1K-byte frame. The remaining three bits are not implemented.

(b) The slave uses two quadrants.

Each quadrant has to be in one of these groups: (Quad 0 and Quad 1) or (Quad 2 and Quad 3).

For the group Quad0/Quad1, the bit quadrant 0 protects both quadrants 0 and 1. The bit quadrant 1 is not implemented.

For the group Quad2/Quad3, the bit quadrant 2 protects both quadrants 2 and 3. The bit quadrant 3 is not implemented.

(c) The slave uses only one quadrant.

In this case, the bit, as specified in [Table 2-89](#), protects the slave.

The above arrangement is true for all the peripheral select (PS0 to PS31), presented in [Section 2.5.3.6 - Section 2.5.3.12](#). This register holds bits for PS0 to PS7 and is shown in [Figure 2-73](#) and described in [Table 2-89](#).

NOTE: Writes to nonimplemented bits have no effect and reads are 0.

Figure 2-73. Peripheral Protection Set Register 0 (PPROTSET0) [offset = 20h]

LEGEND: R/W = Read/Write; R = Read only; WP = Write in privileged mode only; -n = value after reset

| Bit | Field | Value | Description |
|------|-------------------------|-------|---|
| 31-0 | PS[7-0]QUAD[3-0]PROTSET | 0 | Peripheral select quadrant protection set. <i>Read:</i> The peripheral select quadrant can be written to and read from in both user and privileged modes. <i>Write:</i> The bit is unchanged. |
| | | 1 | <i>Read:</i> The peripheral select quadrant can be written to only in privileged mode, but it can be read in both user and privileged modes. <i>Write:</i> The corresponding bit in PMPROTSET0 and PMPROTCLR0 registers is set to 1. |

2.5.3.6 Peripheral Protection Set Register 1 (PPROTSET1)

There is one bit for each quadrant for PS8 to PS15. The protection scheme is described in [Section 2.5.3.5](#). This register is shown in [Figure 2-74](#) and described in [Table 2-90](#).

NOTE: Only those bits that have a slave at the corresponding bit position are implemented. Writes to nonimplemented bits have no effect and reads are 0.

| | | 1 | <i>Read:</i> The peripheral select quadrant can be written to only in privileged mode, but it can be read in both user and privileged modes. <i>Write:</i> The corresponding bit in PMPROTSET1 and PMPROTCLR1 registers is set to 1. |

2.5.3.7 Peripheral Protection Set Register 2 (PPROTSET2)

There is one bit for each quadrant for PS16 to PS23. The protection scheme is described in [Section 2.5.3.5](#). This register is shown in [Figure 2-75](#) and described in [Table 2-91](#).

NOTE: Only those bits that have a slave at the corresponding bit position are implemented. Writes to nonimplemented bits have no effect and reads are 0.

Power Management Module (PMM)

This chapter describes the power management module (PMM).

| Topic | Page |
|--------------------------------|-------------|
| 3.1 Overview | 209 |
| 3.2 Power Domains | 211 |
| 3.3 PMM Operation..... | 212 |
| 3.4 PMM Registers | 215 |

3.1 Overview

This microcontroller is part of the Hercules family of microcontrollers from Texas Instruments for safety-critical applications. Several functions are implemented on this microcontroller targeted towards varied applications. The core logic is divided into several domains that can be independently turned on or off based on the application's requirements. This allows an application to reduce the leakage current for a core domain that has modules that are not being used by the application.

This chapter describes the Power Management Module (PMM). The PMM provides memory-mapped registers that control the states of the supported power domains. The PMM includes interfaces to the Power Mode Controller (PMC) and the Power State Controller (PSCON). The PMC and PSCON control the power up/down sequence of each power domain.

3.1.1 Main Features of the Power Management Module (PMM)

The main features of the PMM implemented on the microcontroller are:

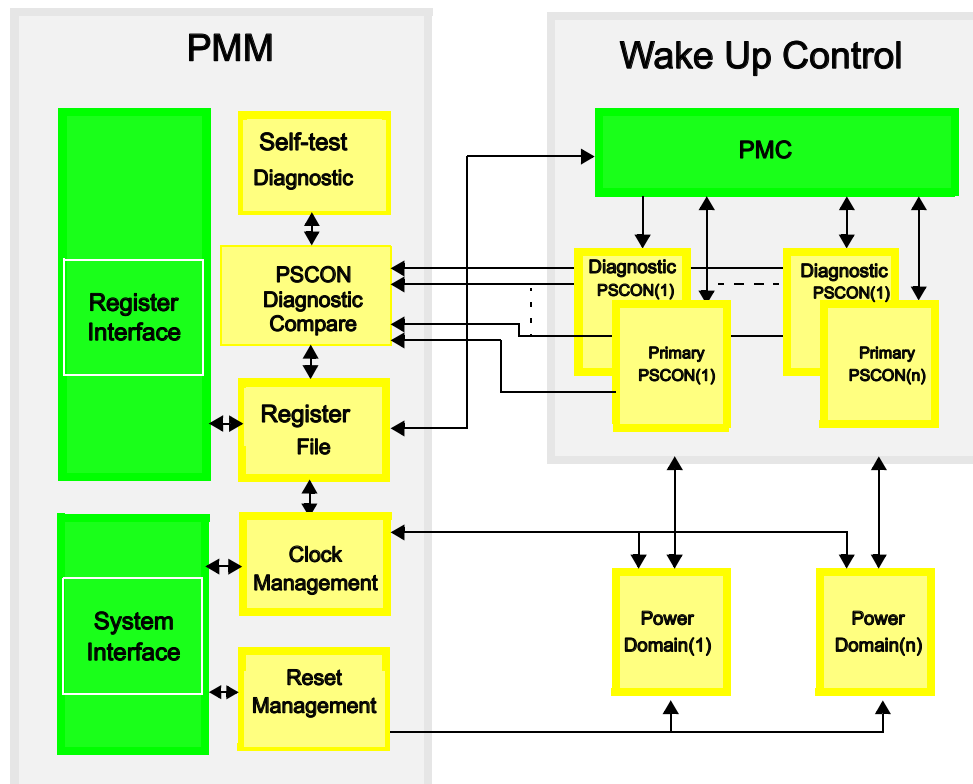

- Supports 5 logic power domains: PD1, PD2, PD3, PD4, and PD5
- Supports 2 memory-only power domains: RAM_PD1, RAM_PD2
- Manages the clocks for each power domain
- Manages the resets to each power domain
- Includes failsafe compare logic to continuously monitor the states of each power domain
- Supports diagnostic and self-test logic to validate failsafe compare logic

3.1.2 Block Diagram

Figure 3-1 is a block diagram of the PMM. The PMM consists of several key components:

- Register interface – the PMM control registers are mapped to the device memory space and start at address 0xFFFF0000.
- System Interface – the PMM receives the clocks, resets, errors and all other control signals through this interface.
- PSCON Diagnostic Compare – this block compares the outputs of each primary PSCON and the respective diagnostic PSCON implemented for failsafe safety.
- Self-Test Diagnostic – this block contains the logic to place the PSCON diagnostic compare block in a self-test mode in order to test the failsafe feature.
- Clock management – the PMM provides independent clock gating and handshaking controls for each power domain and also generates the clock domains for each power domain.
- Reset Management – the PMM provides independent reset signals for each power domain.
- Power State Controller (PSCON) – The PSCON is a finite state machine that controls the power sequence of a power domain from one state to another. Each power domain is controlled by one dedicated PSCON.
- Power Domain – A power domain is a group of logic and/or memories which is separated from the global power supply via power switches. These power switches are controlled by the PSCON and can be turned on or off.

Figure 3-1. PMM Block Diagram

3.2 Power Domains

Figure 3-2 shows the core and memory power domains implemented on the microcontroller.

This device has 7 separate core power domains:

- PD1 is an always-ON domain and is not controlled by PMM. It contains the CPU as well as other principal modules and the interconnect required for operation of the microcontroller. This domain also includes 64KB of the tightly-coupled RAM. The PD1 can operate on its own even when all the other core power domains are turned off by the PMM. Note that all I/Os are in this always-ON domain as well.

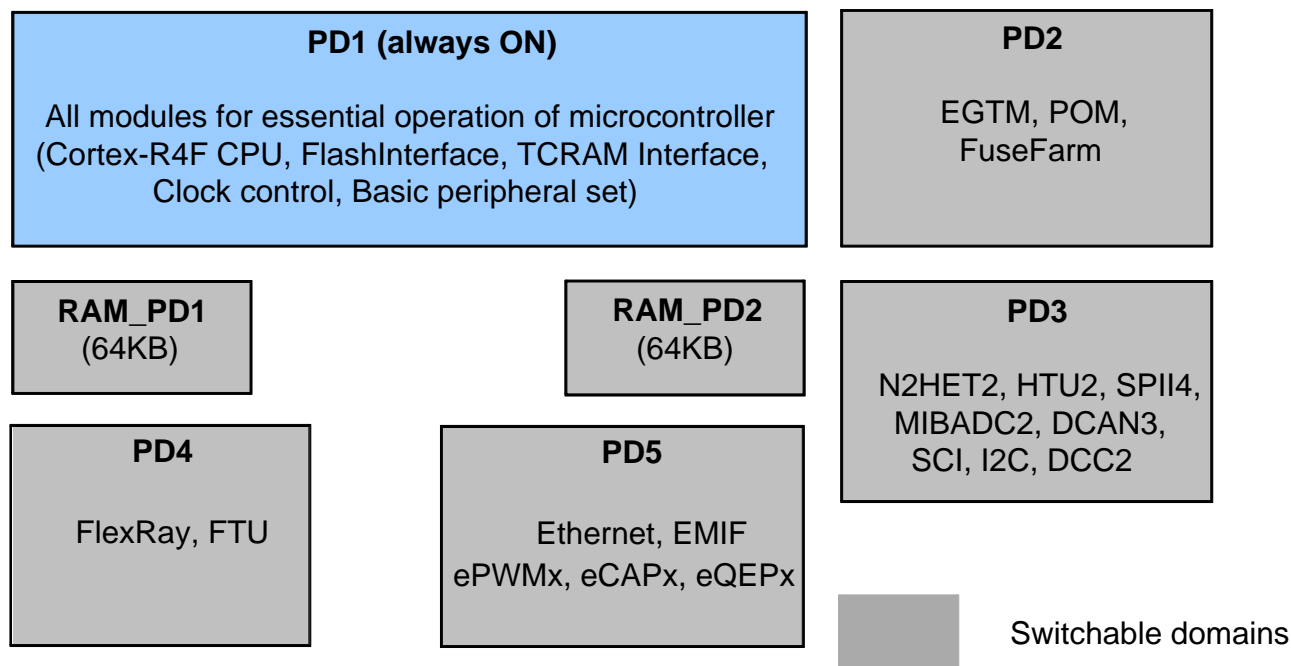

Core power domains PD2 through PD5 and RAM_PD1 through RAM_PD2 are controlled by the PMM.

- PD2 contains the Parameter Overlay Module (POM) and test logic.
- PD3 contains some additional peripheral modules as an enhanced configuration over and above the peripheral set available in PD1. These include a second High-End Timer (N2HET2) with its dedicated transfer unit (HTU2), a second Analog-to-Digital Converter (ADC2), a Serial Communication Interface (SCI), an Inter-Integrated Circuit controller (I2C), a third Controller Area Network controller (DCAN3), and a fourth Serial Peripheral Interface module (SPI4).
- PD4 contains the FlexRay controller and its dedicated transfer unit (FTU).
- PD5 contains the Ethernet Controller (EMAC), External Memory Interface (EMIF), Enhanced Pulse Width Modulator (ePWMx), Enhanced Capture (eCAPx), and Enhanced Quadrature Encoder Pulse (eQEPx), as well as some components of the interconnect fabric required by these modules.
- RAM_PD1 and RAM_PD2 each contain 64KB of tightly-coupled RAM.

NOTE: Switching of Power Domains

The microcontrollers only support static switching of the power domains. That is, the power domains can be turned ON or OFF one time during device initialization. Once configured, it is not allowed to change the state of a power domain without first asserting a system reset.

Figure 3-2. Core Power Domains

3.3 PMM Operation

It is important to understand some fundamental concepts beforehand.

3.3.1 Power Switch

A power domain gets its power supply via a power switch. The power switch creates a link between the global core supply plane and the local switchable power domain supply. Each power domain uses multiple power switches, which are daisy-chained together.

3.3.2 Power Domain State

Each core power domain can be in one of three states: Active, Idle, or Off.

In the **active** state, a power domain is fully powered with normal supply voltage.

In the **idle** state, all clocks to a power domain are turned off (driven low). The supply voltage is still maintained at the normal level.

In the **off** state, a power domain is completely cut off from the power supply.

3.3.3 Default Power Domain State

The default state of each power domain, except for PD1, is controlled by TI during production testing via programming of individual bits within the reset configuration word in the TI-OTP sector of flash bank 0. This allows each power domain to default to either the active state or the off state.

3.3.4 Disabling a Power Domain Permanently

TI can also permanently disable any power domain, except for PD1. This is also controlled by programming of individual bits within the reset configuration word in the TI-OTP sector of flash bank 0.

3.3.5 Changing Power Domain State

A domain can only change state when commanded by the application. Each domain has an associated 4-bit key to define the intended power state. When the correct key is programmed, the PMM initiates the sequence to transition that domain to the commanded state.

A power state transition is considered complete only when every single power switch for that domain has switched over to the commanded state.

3.3.5.1 Turning a Power Domain Off

It is necessary to turn off all clocks going to a power domain before that domain can be powered down. PMM contains the hardware interlocks to handle this. Each power domain has an associated memory-mapped register which allows the application to turn off clocks to that power domain.

Steps to power down a domain with logic – PD2, PD3, PD4, PD5:

1. Write to the PDCLK_DISx register to disable all clocks to the power domain.
2. Write 0xA to the LOGICPDPWRCTRL0 register to power down each domain.
3. Poll for LOGICPDPWRSTATx.LOGICPDPWR_STATx to become "00". The power domain is now powered down.

A power domain with only SRAM macros does not have a clock input, so the sequence is shorter. This applies to RAM_PD1 and RAM_PD2 power domains shown in [Figure 3-2](#):

1. Write the correct key to the MEMPDONx register to power down the domain.
2. Poll for MEMPDWRSTATx.MEMPDPWR_STATx to become "00". The power domain is now powered down.

3.3.5.2 Turning a Power Domain On

A power domain can be turned on by writing the correct key to the LOGICPDPWRCTRL0.LOGICPDONx or MEMPDWPWRCTRL0.MEMPDONx. PMM will automatically restart the clocks to the power domain once the power is restored if the “automatic clock enable upon wake up” option is selected. If this option is not selected, the application can turn on clocks to the power domain by clearing the PDCLK_DIS register. The application must poll the LOGICPDPWRSTATx.DOMAIN_ONx to ensure that the power has been fully restored before enabling the clocks.

NOTE: If a power domain has been permanently disabled by TI, the application cannot turn this power domain ON. No error is generated if the application attempts to do so.

3.3.6 Reset Management

PMM handles the reset sequence for each power domain. When a power domain is turned on from an off state, the PMM will reset the power domain to ensure that all logic begins in its default reset state.

PMM generates nPORRST (power-on reset), nRST (system reset), nPRST (peripheral reset), and nTRST (test / debug logic reset) for each domain.

3.3.7 Diagnostic Power State Controller (PSCON)

Each power domain state is controlled by a primary PSCON. There is a second PSCON as well for each power domain. This is the diagnostic PSCON. All power management inputs to a power domain are controlled only by the primary PSCON. All power management outputs from the power domain are fed back to both the primary and the diagnostic PSCON.

The PMM commands both the PSCON identically so that they are always in a lock-step operating mode. A dedicated compare unit checks the outputs of the two PSCON modules on every cycle.

3.3.8 PSCON Compare Block

The diagnostic compare block can operate in one of four modes:

3.3.8.1 Lock-Step Mode

This is the default mode of operation of the PSCON compare block. The PSCON diagnostic compare block compares the outputs from the two PSCONs on every cycle. Any mismatch in the PSCON outputs is indicated as a PSCON compare error. This error signal is mapped to the Error Signaling Module's (ESM) Group1 channel 38. The application can define the response to this error.

3.3.8.2 Self-Test Mode

A self-test mechanism is provided to check the PSCON compare logic for faults. The compare error signal output is disabled in self-test mode. The PSCON diagnostic compare block generates two types of patterns during self-test mode: compare match test followed by compare mismatch test. During the self-test, each test pattern is applied on both PSCON signal ports of the PSCON diagnostic compare block and then is clocked for one cycle. The duration of the self-test is 24 cycles. Any detected fault is indicated as a self-test error, mapped to ESM group1 channel 39. If no fault is detected, the self-test complete flag is set.

The application can poll for this flag to be set and then switch the mode of the PSCON compare block back to lock-step mode by writing to the mode key register.

NOTE: PSCON operation when compare block is in self-test mode

When the PSCON compare block is in its self-test mode, both PSCONs continue to function normally. However, there is no comparison done on the PSCON outputs.

Compare match test:

An identical vector is applied to both input ports at the same time, thereby expecting a compare match. If the compare unit produces a mismatch then the self-test error flag is set and the self-test error signal is generated. The compare match test is terminated if a compare mismatch is detected. The compare match test takes 4 cycles to complete when the test passes.

Compare mismatch test:

A vector with all 1's is applied to the PSCON diagnostic compare block's primary input port and the same input is also applied to the secondary input port but with one bit flipped starting from bit position 0. The unequal vectors should cause the PSCON diagnostic compare block to generate a compare mismatch at bit position 0. In case a mismatch is not detected, a self-test error is indicated. This compare mismatch test algorithm is repeated until every single bit position is verified on both PSCON signal ports.

3.3.8.3 Error-Forcing Mode

This mode is designed specifically to ensure that the error signal output from the PSCON compare block is not stuck inactive. In this mode, a test pattern is applied to the PSCON related inputs of the compare logic to force an error. During error forcing mode, both the error signal and the self-test error signal will be asserted to the ESM. The application can clear flags for ESM group1 channel 38 and ESM group1 channel 39 once the error is flagged. If the two ESM flags do not get set, this indicates that the PSCON compare error signal is stuck inactive and cannot be relied upon to detect a PSCON mismatch.

3.3.8.4 Self-Test Error-Forcing Mode

In this mode, an error is forced so that the self-test error output from the PSCON compare block is activated. The application can clear the flag for ESM group1 channel 39 once the error is flagged. If the ESM group1 channel 39 flag does not get set, this indicates that the PSCON compare block self-test error signal is stuck inactive and there is no self-test mechanism available for the PSCON compare block.

3.3.8.5 PMM Operation During CPU Halt Debug Mode

No compare errors are generated when the CPU is halted in debug mode, regardless of the mode of the diagnostic compare block. No status flags are updated in this mode. Normal operation of the compare block is resumed once the CPU exits the debug mode.

3.4 PMM Registers

[Table 3-1](#) lists the memory-mapped registers for the PMM. All register offset addresses not listed in [Table 3-1](#) should be considered as reserved locations and the register contents should not be modified. The address offset is specified from the base address of FFFF 0000h. Any access to an unimplemented location within the PMM register frame will generate a bus error that results in an Abort exception.

Table 3-1. PMM Registers

| Offset | Acronym | Register Name | Section |
|--------|-----------------|--|--------------------------------|
| 0h | LOGICPDPWRCTRL0 | Logic Power Domain Control Register 0 | Section 3.4.1 |

Read in User and Privileged Mode.</p> <p>0h = Memory power domain RAM_PD1 is switched OFF</p> <p>1h = Reserved</p> <p>2h = Reserved</p> <p>3h = Logic power domain RAM_PD1 is in Active state</p> |

3.4.11 MEMPDWRSTAT1 Register (Offset = 84h) [reset = X]

MEMPDPWRSTAT1 is shown in Figure 3-13 and described in Table 3-12.

This is a read-only register. All writes are ignored.

The default values of the control fields are determined by the device reset configuration word stored in the TI-OTP region of flash bank 0.

3.4.19 ISODIAGSTAT Register (Offset = C0h) [reset = 0h]

ISODIAGSTAT is shown in [Figure 3-21](#) and described in [Table 3-20](#).

There is an ISO_DIAG cell and is implemented separately for each logic power domain. This is a special tie-off cell that reads a value of 1 when the logic power domain is powered up. This cell has an isolation value of 0. That is, when this logic power domain is turned off, this cell will read 0. The ISO_DIAG statuses for each logic power domain is reflected in the ISODIAGSTAT register. The application can poll this diagnostic register to make sure that a domain that has been commanded to turn off has actually received the command.

I/O Multiplexing and Control Module (IOMM)

This chapter describes the I/O Multiplexing and Control Module (IOMM).

| Topic | Page |
|--|------------|
| 4.1 Overview | 239 |
| 4.2 Main Features of I/O Multiplexing Module (IOMM) | 239 |
| 4.3 Control of Multiplexed Outputs | 239 |
| 4.4 Control of Multiplexed Inputs | 240 |
| 4.5 Control of Special Multiplexed Options | 241 |
| 4.6 Safety Features | 250 |
| 4.7 IOMM Registers | 251 |
| 4.8 Output Multiplexing and Control..... | 264 |

4.1 Overview

This chapter describes the overall features of the module that controls the I/O multiplexing on the device. The mapping of control registers to multiplexing options is specified in [Section 4.8](#).

4.2 Main Features of I/O Multiplexing Module (IOMM)

The IOMM contains memory-mapped registers (MMR) that control device-specific multiplexed functions. The safety and diagnostic features of the IOMM are:

- Kicker mechanism to protect the MMRs from accidental writes
- Error indication for access violations

4.3 Control of Multiplexed Outputs

The signal multiplexing controlled by each memory-mapped control register (PINMMRn) is described in [Table 4-21](#). Each byte in the PINMMRs control the functionality output on a single terminal. Consider the following example for the PINMMR10 control register.

Figure 4-1. PINMMR10 Control Register, Address = FFFF EB38h

LEGEND: R/W = Read/Write; R = Read only; WP = Write in privileged mode only; -n = value after reset

- Consider the multiplexing controlled by PINMMR10[23–16]. These bits control the multiplexing between the EMIF_nCS[0] and N2HET2[7] on the ball N17 of the 337BGA package for this device. The default function on the N17 ball is EMIF_nCS[0]. This is dictated by bit 16 of the PINMMR10 register being set.
- If the application wants to use N17 as an N2HET2[7] signal, then bit 16 of PINMMR10 must be cleared and bit 18 must be set.
- Each feature of the output function is determined by the function selected to be output on a terminal.

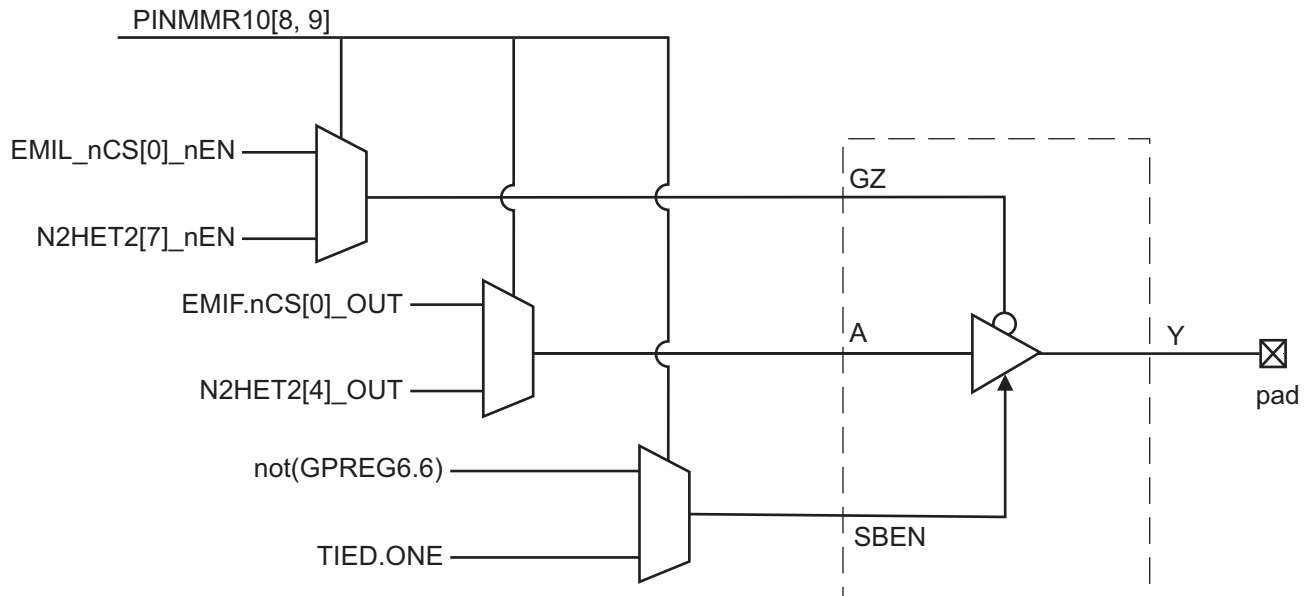

For example, the ball N17 on the 337BGA package is driven by an output buffer with an 8mA drive strength and which supports the adaptive impedance control mode for reduced electromagnetic emissions. This output buffer has the following signals: A (signal to be output), GZ (output enable), SBEN (Standard Buffer Enable) and LPM (Low Power Mode). Each of these signals is an output of a multiplexor which allows the selected function to control all available features of the output buffer.

- The PINMMR control registers are used to implement a one-hot encoding scheme for selecting the multiplexed function.
 - For example, for the N17 ball on the 337BGA package for this device at least one out of bit 16 or bit 18 must be set.
 - If the application clears both bits 16 and 18, then the default function, EMIF_nCS[0], will be selected for output on N17.
 - If the application sets both bits 16 and 18, then the default function will be selected for output on N17.
 - If the application sets one or more reserved bit(s) within the byte 23–16, then the default function

will be selected for output on N17.

Figure 4-2 shows the multiplexing between the output functions for the N17 ball. This terminal uses an 8mA low-EMI output buffer.

Figure 4-2. Output Multiplexing Example

4.4 Control of Multiplexed Inputs

The microcontrollers are available in two package options – 337-ball grid array (BGA) and 144-pin Quad Flat Pack (QFP). Input multiplexing is not required for the 337BGA package. For the 144QFP package, some signals have a multiplexor implemented on their input side. The selection between the two input paths is done by a combination of two control registers. These registers are described in Table 4-1.

Table 4-1. Input Multiplexing on 144QFP Parts

| Signal | 144QFP Dedicated Input Pin # | 144QFP Multiplexed Input Pin # | A, Output Control for Muxed Pin | B, Input Control for Muxed Pin |
|------------|------------------------------|--------------------------------|---------------------------------|--------------------------------|
| SPI4SIMO | – | 30 | PINMMR5[9] | PINMMR23[16] |
| SPI4SOMI | – | 31 | PINMMR5[17] | PINMMR23[24] |
| SPI4CLK | – | 25 | PINMMR5[1] | PINMMR23[8] |
| SPI4NENA | – | 23 | PINMMR4[17] | PINMMR24[0] |
| SPI4NCS[0] | – | 24 | PINMMR4[25] | PINMMR24[8] |
| N2HET1[17] | – | 130 | PINMMR20[17] | PINMMR24[16] |
| N2HET1[19] | – | 40 | PINMMR8[9] | PINMMR24[24] |
| N2HET1[23] | – | 96 | PINMMR12[17] | PINMMR25[8] |
| N2HET1[25] | – | 37 | PINMMR7[9] | PINMMR25[16] |
| N2HET1[27] | – | 4 | PINMMR0[26] | PINMMR25[24] |
| N2HET1[29] | – | 3 | PINMMR0[18] | PINMMR26[0] |
| N2HET1[31] | – | 54 | PINMMR9[10] | PINMMR26[8] |
| GIOB[2] | 142 | 55 | PINMMR29[16] | PINMMR29[16] |

For signals with a “–” in the column for dedicated input pin #, these signals do have a dedicated pad on the die. The default input for these signals comes from the dedicated pad. To be able to drive in the input from the multiplexed pins on the 144QFP package, the IOMM registers need to be configured.

Table 4-1 shows two controls for each of these signals: A and B.

A indicates the control register bit to be set to enable the corresponding signal to be output on the multiplexed pin.

B is another control register bit that is used to select between the dedicated input terminal and the multiplexed pin.

- The input to a module comes from the **dedicated** pad when the condition **[not(A) or (A AND B)] = TRUE**.
- The input to a module comes from the **multiplexed** pin when the condition **[A and not(B)] = TRUE**.

NOTE: Inputs are broadcast to all multiplexed functions

The input signals are broadcast to all modules hooked up to a terminal. The application must ensure that modules that are not being used in the application do not react to a change on their input functions. For example, a GIO signal toggle can trigger an interrupt request, when the application actually is using the function multiplexed with this GIO signal.

Figure 4-3. Input Multiplexing Example

4.5 Control of Special Multiplexed Options

Several of the PINMMR registers are used to control specific functions on this microcontroller. These are described now.

4.5.1 Control of SDRAM clock (EMIF_CLK)

PINMMR29[8] is set by default. This blocks the EMIF SDRAM clock signal (EMIF_CLK) from being output from the microcontroller. If the EMIF is used to connect to an external SDRAM module, then the application must enable the SDRAM clock output by clearing the PINMMR29[8] bit.

4.5.2 Control for other EMIF Outputs

There are some EMIF address and control signals that are multiplexed with N2HET2 signals. For applications that require the use of these N2HET2 signals, it is inconvenient if the EMIF starts driving these address and control signals as output after reset is released and before the application can configure the I/O Multiplexing Module registers. Therefore, these EMIF signals are blocked from being output by default. This is done by using the bit 31 of the system module General Purpose Control Register (GPREG1). This bit is cleared (0) by default. In this condition, these EMIF/N2HET2 terminals are configured as inputs and pulled down. An application that requires the EMIF functionality must set the GPREG1[31] bit. This causes the EMIF address and control signals to then be output on the EMIF/N2HET2 terminals when the EMIF functionality is selected via the IOMM output multiplexing control registers.

4.5.3 Control for Fast Mode for Synchronous and Asynchronous EMIF

The EMIF on this microcontroller implements a "fast mode" for both the synchronous and asynchronous interfaces. There are some critical timing paths on read accesses to external asynchronous as well as synchronous memories. The fast mode allows the clock to the capture flops inside the EMIF module to be pushed in order to capture the incoming data correctly. The fast mode for asynchronous interface is enabled by setting PINMMR29[18] and the fast mode for the synchronous interface is enabled by setting PINMMR29[17].

4.5.4 Control of Ethernet Controller Mode

PINMMR29[24] is set by default. This bit is used to enable the Reduced Media Independent Interface of the Ethernet controller. If the application desires to use the Media Independent Interface of the Ethernet controller, then the PINMMR29[24] must be cleared.

4.5.5 Control of ADC Trigger Events

The microcontrollers contain two Analog-to-Digital Converter modules: ADC1 and ADC2. The ADC conversions can be started using a rising or falling or both edges as the trigger event. Both the ADC modules support up to eight event trigger inputs. There are two sets of these 8 inputs for each ADC. The option for each of these 8 inputs are controlled by registers in the I/O multiplexing module as shown in [Table 4-2](#) and [Table 4-3](#).

Table 4-2. ADC1 Trigger Event Selection

| Group Source Select, G1SRC, G2SRC or EVSRC | Event # | Trigger Event Signal | | | | |
|--|---------|---------------------------|-------------------------------------|----------------------|------------|---------------------------------------|
| | | PINMMR30[0] = 1 (default) | PINMMR30[0] = 0 and PINMMR30[1] = 1 | | | |
| | | | Option A | Control for Option A | Option B | Control for Option B |
| 000 | 1 | AD1EVT | AD1EVT | — | AD1EVT | — |
| 001 | 2 | N2HET1[8] | N2HET2[5] | PINMMR30[8] = 1 | ePWM_B | PINMMR30[8] = 0 and PINMMR30[9] = 1 |
| 010 | 3 | N2HET1[10] | N2HET1[27] | — | N2HET1[27] | — |
| 011 | 4 | RTI Compare 0 Interrupt | RTI Compare 0 Interrupt | PINMMR30[16] = 1 | ePWM_A1 | PINMMR30[16] = 0 and PINMMR30[17] = 1 |
| 100 | 5 | N2HET1[12] | N2HET1[17] | — | N2HET1[17] | — |
| 101 | 6 | N2HET1[14] | N2HET1[19] | PINMMR30[24] = 1 | N2HET2[1] | PINMMR30[24] = 0 and PINMMR30[25] = 1 |
| 110 | 7 | GIOB[0] | N2HET1[11] | PINMMR31[0] = 1 | ePWM_A2 | PINMMR31[0] = 0 and PINMMR31[1] = 1 |
| 111 | 8 | GIOB[1] | N2HET2[13] | PINMMR31[8] = 1 | ePWM_AB | PINMMR31[8] = 0 and PINMMR31[9] = 1 |

Table 4-3. ADC2 Trigger Event Selection

| Group Source Select, G1SRC, G2SRC or EVSRC | Event # | Trigger Event Signal | | | | |
|--|---------|---------------------------|-------------------------------------|----------------------|----------|----------------------|
| | | PINMMR30[0] = 1 (default) | PINMMR30[0] = 0 and PINMMR30[1] = 1 | | | |
| | | | Option A | Control for Option A | Option B | Control for Option B |
| 000 | 1 | AD2EVT | AD1EVT | — | AD1EVT | — |

Table 4-3. ADC2 Trigger Event Selection (continued)

| | | | | | | |
|-----|---|----------------------------|----------------------------|------------------|------------|--|
| 001 | 2 | N2HET1[8] | N2HET2[5] | PINMMR31[16] = 1 | ePWM_B | PINMMR31[16] = 0 and PINMMR31[17] = 1 |
| 010 | 3 | N2HET1[10] | N2HET1[27] | — | N2HET1[27] | — |
| 011 | 4 | RTI Compare 0 Interrupt | RTI Compare 0 Interrupt | PINMMR31[24] = 1 | ePWM_A1 | PINMMR31[24] = 0 and PINMMR31[25] = 1 |
| 100 | 5 | N2HET1[12] | N2HET1[17] | — | N2HET1[17] | — |
| 101 | 6 | N2HET1[14] | N2HET1[19] | PINMMR32[0] = 1 | N2HET2[1] | PINMMR32[0] = 0 and PINMMR32[1] = 1 |
| 110 | 7 | GIOB[0] | N2HET1[11] | PINMMR32[8] = 1 | ePWM_A2 | PINMMR32[8] = 0 and PINMMR32[9] = 1 |
| 111 | 8 | GIOB[1] | N2HET2[13] | PINMMR32[16] = 1 | ePWM_AB | PINMMR32[16] = 0 and PINMMR32[17] = 1 |

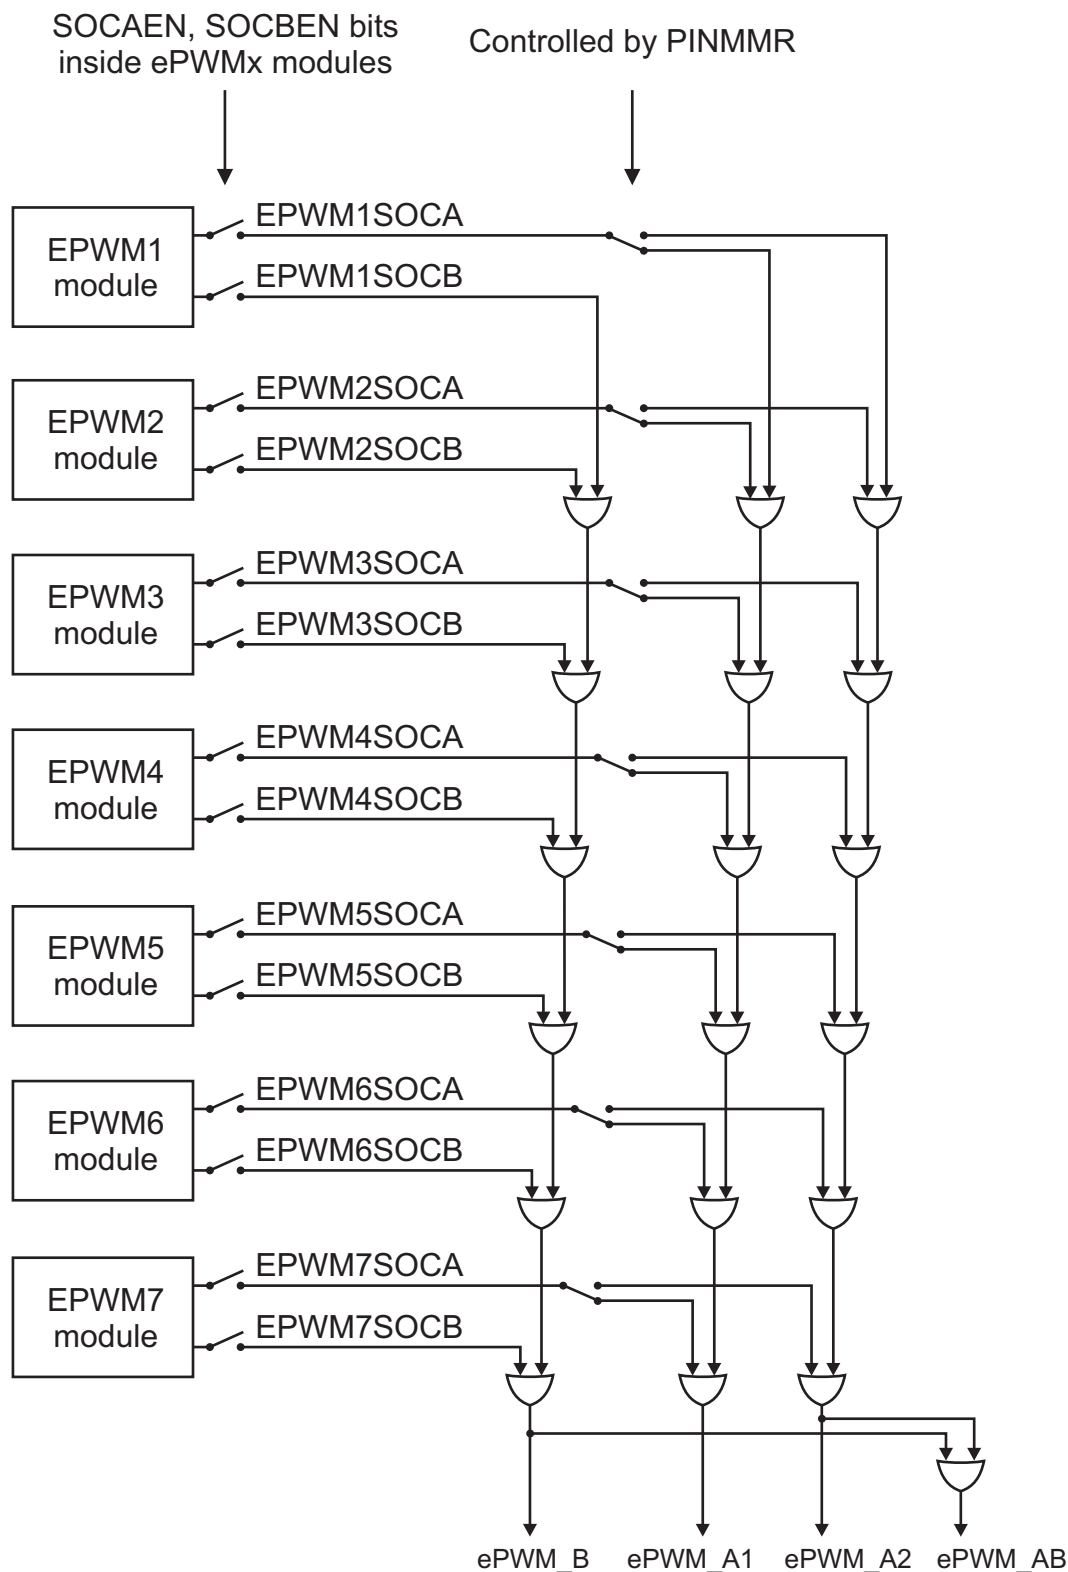

4.5.6 Control for ADC Event Trigger Signal Generation from ePWMx Modules

This microcontroller implements 7 ePWM modules. Each of these modules generate two outputs, SOCA (Start Of Conversion) and SOCB, for use in triggering the on-chip ADC modules. Registers from the I/O multiplexing module are used to control the logic for generation of the ePWM_A1, ePWM_A2, ePWM_AB, and ePWM_B signals from these ePWMx_SOCA and ePWMx_SOCB signals.

The logic equations for the 4 outputs from the combinational logic shown in [Figure 4-4](#) are:

- B = SOC1B or SOC2B or SOC3B or SOC4B or SOC5B or SOC6B or SOC7B
- A1 = [SOC1A and not(SOC1A_SEL)]
[SOC2A and not(SOC2A_SEL)]
[SOC3A and not(SOC3A_SEL)]
[SOC4A and not(SOC4A_SEL)]
[SOC5A and not(SOC5A_SEL)]
[SOC6A and not(SOC6A_SEL)]
[SOC7A and not(SOC7A_SEL)]
- A2 = [SOC1A and SOC1A_SEL]
[SOC2A and SOC2A_SEL]
[SOC3A and SOC3A_SEL]
[SOC4A and SOC4A_SEL]
[SOC5A and SOC5A_SEL]
[SOC6A and SOC6A_SEL]
[SOC7A and SOC7A_SEL]
- AB = B or A2

Figure 4-4. ADC Trigger Event Signal Generation from ePWMx

The SOCxA_SEL signals used in the above logic equations are generated using registers in the I/O multiplexing module.

- PINMMR35[0] defines the value of SOC1A_SEL. This bit is set by default and can be cleared by the application.
- PINMMR35[8] defines the value of SOC2A_SEL. This bit is set by default and can be cleared by the application.
- PINMMR35[16] defines the value of SOC3A_SEL. This bit is set by default and can be cleared by the application.
- PINMMR35[24] defines the value of SOC4A_SEL. This bit is set by default and can be cleared by the application.
- PINMMR36[0] defines the value of SOC5A_SEL. This bit is set by default and can be cleared by the application.
- PINMMR36[8] defines the value of SOC6A_SEL. This bit is set by default and can be cleared by the application.
- PINMMR36[16] defines the value of SOC7A_SEL. This bit is set by default and can be cleared by the application.

4.5.7 Control for Generating Interrupt Upon External Fault Indication to N2HETx

The N2HET module on this microcontroller allows the application to selectively disable any PWM output from the N2HET module whenever a fault condition is indicated to the N2HET. This fault condition is input to the N2HET module via the N2HETx_PIN_nDIS input signal. It is important for the CPU to be notified with an interrupt whenever this fault condition is indicated to the N2HET module.

The PIN_nDIS signal for the N2HET1 module comes from the GIOA[5] terminal, and the application can enable the interrupt generation for whenever the GIOA[5] terminal is driven low.

The PIN_nDIS signal for the N2HET2 module comes from the MibSPI3_nCS[0] / AD2EVT terminal. These signals do not offer the capability of generating an interrupt when they are driven low. Therefore, the input from this terminal can optionally be connected to the GIOB[2] input. This connection is enabled by a register in the I/O multiplexing module. This is the PINMMR29[16].

4.5.8 Control for Enabling Clocks to ePWMx Modules

The VCLK4 domain is used as the clock for the ePWMx modules. This clock can be individually gated off when one or more of the ePWMx modules are not being used.

- PINMMR37[8] is set by default and enables the clock to the ePWM1. The application can clear this bit to disable the clock to the ePWM1.
- PINMMR37[16] is set by default and enables the clock to the ePWM2. The application can clear this bit to disable the clock to the ePWM2.
- PINMMR37[24] is set by default and enables the clock to the ePWM3. The application can clear this bit to disable the clock to the ePWM3.
- PINMMR38[0] is set by default and enables the clock to the ePWM4. The application can clear this bit to disable the clock to the ePWM4.
- PINMMR38[8] is set by default and enables the clock to the ePWM5. The application can clear this bit to disable the clock to the ePWM5.
- PINMMR38[16] is set by default and enables the clock to the ePWM6. The application can clear this bit to disable the clock to the ePWM6.
- PINMMR38[24] is set by default and enables the clock to the ePWM7. The application can clear this bit to disable the clock to the ePWM7.

4.5.9 Control for Enabling Clocks to eCAPx Modules

The VCLK4 domain is used as the clock for the eCAPx modules. This clock can be individually gated off when one or more of the eCAPx modules are not being used.

- PINMMR39[0] is set by default and enables the clock to the eCAP1. The application can clear this bit to disable the clock to the eCAP1.
- PINMMR39[8] is set by default and enables the clock to the eCAP2. The application can clear this bit to disable the clock to the eCAP2.
- PINMMR39[16] is set by default and enables the clock to the eCAP3. The application can clear this bit to disable the clock to the eCAP3.
- PINMMR39[24] is set by default and enables the clock to the eCAP4. The application can clear this bit to disable the clock to the eCAP4.
- PINMMR40[0] is set by default and enables the clock to the eCAP5. The application can clear this bit to disable the clock to the eCAP5.
- PINMMR40[8] is set by default and enables the clock to the eCAP6. The application can clear this bit to disable the clock to the eCAP6.

4.5.10 Control for Enabling Clocks to eQEPx Modules

The VCLK4 domain is used as the clock for the eQEPx modules. This clock can be individually gated off when one or more of the eQEPx modules are not being used.

- PINMMR40[16] is set by default and enables the clock to the eQEP1. The application can clear this bit to disable the clock to the eQEP1.
- PINMMR40[24] is set by default and enables the clock to the eQEP2. The application can clear this bit to disable the clock to the eQEP2.

4.5.11 Control for Synchronizing Time Bases for All ePWMx Modules

The ePWMx modules implement a mechanism that allows their time bases to be synchronized. This is done by using a signal called TBCLKSYNC, which is a common input to all the ePWMx modules. This TBCLKSYNC is generated by a register bit in the I/O multiplexing module. PINMMR37[1] is the TBCLKSYNC signal. This bit is clear (0) by default.

When TBCLKSYNC = 0, the time-base clock of all ePWMx modules is stopped. This is the default condition.

When TBCLKSYNC = 1, the time-base clocks of all ePWMx modules are started aligned to the rising edge of the TBCLKSYNC signal.

The correct procedure for enabling and synchronizing the time-base clocks of all the ePWMx modules is:

1. Enable the clocks to the desired individual ePWMx modules if they have been disabled
2. Set TBCLKSYNC = 0. This will stop the time-base clocks of any enabled ePWMx module.
3. Configure the time-base clock prescaler values and desired ePWM modes.
4. Set TBCLKSYNC = 1.

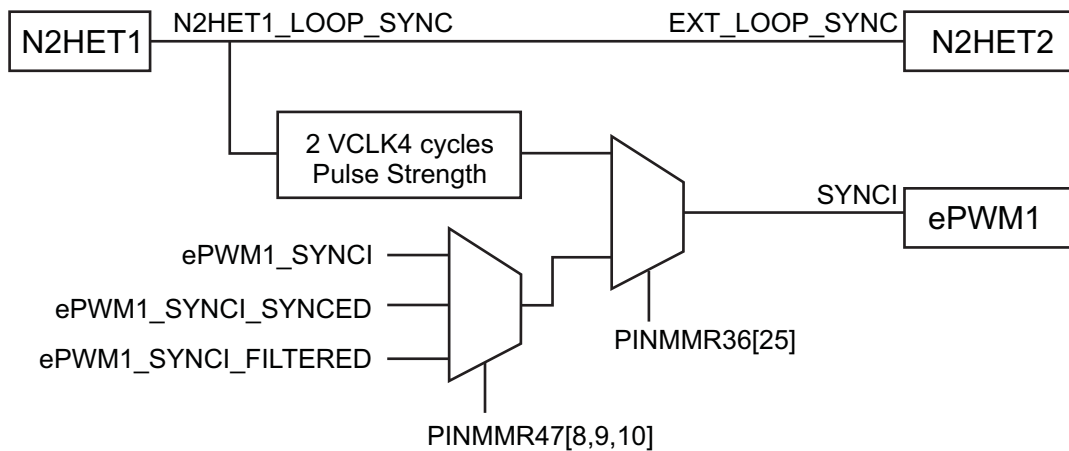

4.5.12 Control for Synchronizing all ePWMx Modules to N2HET1 Module Time-Base

Some applications require a synchronized time base for all PWM signals generated by the microcontroller. The N2HET1 module uses a time base that is created by configuring the high-resolution and loop-resolution prescalers in the N2HET1 module control registers. The N2HET1 module outputs the loop-resolution clock signal (N2HET1_LOOP_SYNC) so that other timer modules on the microcontroller can use it to synchronize their time bases to the N2HET1 loop-resolution clock.

There is a dedicated connection between the N2HET1 and N2HET2 modules, which allows the N2HET2 to use the N2HET1_LOOP_SYNC signal to synchronize its own time base to that of N2HET1.

The seven ePWMx modules can also optionally use the N2HET1_LOOP_SYNC for their time-base synchronization using a specially designed scheme.

Figure 4-5. Synchronizing ePWMx Modules to N2HET1 Time-Base

PINMMR36[25] is used to select between the ePWM1_SYNCI and the stretched N2HET1_LOOP_SYNC signals.

If PINMMR36[25] = 0, the SYNCI input to the ePWM1 comes from the ePWM1_SYNCI device input terminal. This is the default connection.

If PINMMR36[25] = 1, the SYNCI input to the ePWM1 comes from the pulse-stretched N2HET1_LOOP_SYNC signal.

4.5.13 Control for Input Connections to ePWMx Modules

The ePWMx modules take the following signals as input:

- ePWM1_SYNCI: external time-base input to the ePWMx
- nTZ1 through nTZ6: trip-zone inputs to the ePWMx

Of the six trip-zone inputs, three are input from device terminals while the other three are connected to internal error events. Registers from the I/O multiplexing module are used to control various aspects of these input connections to the ePWMx modules.

Table 4-4. Controls for ePWMx Inputs

| Input Signal | Control for Asynchronous Input (default connection) | Control for Double-VCLK4-Synchronized Input | Control for Double-VCLK4-Synchronized and 6-VCLK4-Filtered Input |
|--------------|--|---|--|
| nTZ1 | PINMMR46[16] = 1 | PINMMR46[16] = 0 and PINMMR46[17] = 1 | PINMMR46[17:16] = 00 and PINMMR46[18] = 1 |
| nTZ2 | PINMMR46[24] = 1 | PINMMR46[24] = 0 and PINMMR46[25] = 1 | PINMMR46[25:24] = 00 and PINMMR46[26] = 1 |
| nTZ3 | PINMMR47[0] = 1 | PINMMR47[0] = 0 and PINMMR47[1] = 1 | PINMMR47[1:0] = 00 and PINMMR47[2] = 1 |
| ePWM1_SYNCI | PINMMR47[8] = 1 | PINMMR47[8] = 0 and PINMMR47[9] = 1 | PINMMR47[9:8] = 00 and PINMMR47[10] = 1 |

Of the three internal error events for the trip-zone inputs, nTZ4 is connected to the eQEPx error output signal. There are two eQEP modules on this microcontroller, and registers in the I/O multiplexing module are used to allow a flexible scheme for the connection between the eQEPx error signal and the nTZ4 inputs of the ePWMx modules.

Table 4-5. Controls for eQEPx_ERROR Connection to ePWMx nTZ4 Inputs

| ePWMx Module | Control for nTZ4 = not(eQEP1ERR or eQEP2ERR) (default connection) | Control for nTZ4 = not(eQEP1ERR) | Control for nTZ4 = not(eQEP2ERR) |
|--------------|--|--|--|
| ePWM1 | PINMMR41[0] = 1 | PINMMR41[0] = 0 and PINMMR41[1] = 1 | PINMMR41[1:0] = 00 and PINMMR41[2] = 1 |
| ePWM2 | PINMMR41[8] = 1 | PINMMR41[8] = 0 and PINMMR41[9] = 1 | PINMMR41[9:8] = 00 and PINMMR41[10] = 1 |
| ePWM3 | PINMMR41[16] = 1 | PINMMR41[16] = 0 and PINMMR41[17] = 1 | PINMMR41[17:16] = 00 and PINMMR41[18] = 1 |
| ePWM4 | PINMMR41[24] = 1 | PINMMR41[24] = 0 and PINMMR41[25] = 1 | PINMMR41[25:24] = 00 and PINMMR41[26] = 1 |
| ePWM5 | PINMMR42[0] = 1 | PINMMR42[0] = 0 and PINMMR42[1] = 1 | PINMMR42[1:0] = 00 and PINMMR42[2] = 1 |
| ePWM6 | PINMMR42[8] = 1 | PINMMR42[8] = 0 and PINMMR42[9] = 1 | PINMMR42[9:8] = 00 and PINMMR42[10] = 1 |
| ePWM7 | PINMMR42[16] = 1 | PINMMR42[16] = 0 and PINMMR42[17] = 1 | PINMMR42[17:16] = 00 and PINMMR42[18] = 1 |

4.5.14 Control for Input Connections to eCAPx Modules

Each eCAPx module has a single input from the device terminals. This input can be connected to the eCAPx module in two ways:

1. Double-synchronized using VCLK4, or
2. Double-synchronized using VCLK4 and then filtered through a 6-VCLK4-cycle counter

Registers in the I/O multiplexing module are used to control these input connections for each eCAPx module.

Table 4-6. Controls for eCAPx Inputs

| eCAPx Input | Control for Double-VCLK4-Synchronized Input (default connection) | Control for Double-VCLK4-Synchronized and 6-VCLK4-Filtered Input |
|-------------|--|--|
| eCAP1 | PINMMR43[0] = 0 | PINMMR43[0] = 0 and PINMMR43[1] = 1 |
| eCAP2 | PINMMR43[8] = 0 | PINMMR43[8] = 0 and PINMMR43[9] = 1 |
| eCAP3 | PINMMR43[16] = 0 | PINMMR43[16] = 0 and PINMMR43[17] = 1 |
| eCAP4 | PINMMR43[24] = 0 | PINMMR43[24] = 0 and PINMMR43[25] = 1 |
| eCAP5 | PINMMR44[0] = 0 | PINMMR44[0] = 0 and PINMMR44[1] = 1 |
| eCAP6 | PINMMR44[8] = 0 | PINMMR44[8] = 0 and PINMMR44[9] = 1 |

4.5.15 Control for Input Connections to eQEPx Modules

Each eQEPx module has four inputs from the device terminals. These inputs can be connected to the eQEPx module in two ways:

1. Double-synchronized using VCLK4, or
2. Double-synchronized using VCLK4 and then filtered through a 6-VCLK4-cycle counter

Registers in the I/O multiplexing module are used to control these input connections for each eQEPx module.

Table 4-7. Controls for eQEPx Inputs

| eQEPx Input | Control for Double-VCLK4-Synchronized Input (default connection) | Control for Double-VCLK4-Synchronized and 6-VCLK4-Filtered Input |
|-------------|--|--|
| eQEP1A | PINMMR44[16] = 0 | PINMMR44[16] = 0 and PINMMR44[17] = 1 |
| eQEP1B | PINMMR44[24] = 0 | PINMMR44[24] = 0 and PINMMR44[25] = 1 |
| eQEP1I | PINMMR45[0] = 0 | PINMMR45[0] = 0 and PINMMR45[1] = 1 |
| eQEP1S | PINMMR45[8] = 0 | PINMMR45[8] = 0 and PINMMR45[9] = 1 |
| eQEP2A | PINMMR45[16] = 0 | PINMMR45[16] = 0 and PINMMR45[17] = 1 |
| eQEP2B | PINMMR45[24] = 0 | PINMMR45[24] = 0 and PINMMR45[25] = 1 |
| eQEP2I | PINMMR46[0] = 0 | PINMMR46[0] = 0 and PINMMR46[1] = 1 |
| eQEP2S | PINMMR46[8] = 0 | PINMMR46[8] = 0 and PINMMR46[9] = 1 |

4.6 Safety Features

The IOMM supports certain safety functions that are designed to prevent unintentional changes to the I/O multiplexing configuration. These are described in the following sections.

4.6.1 Locking Mechanism for Memory-Mapped Registers

The IOMM contains a mechanism to prevent any spurious writes from changing any of the PINMMR values. The PINMMRs are locked by default and after any system reset. None of the PINMMRs can be written under this condition. The application can read any of the IOMM registers regardless of the state of the locking mechanism.

- **Enabling Write Access to the PINMMRs**

To enable write access to the PINMMRs, the CPU must write 0x83e70b13 to the kick0 register followed by a write of 0x95a4f1e0 to the kick1 register.

- **Disabling Write Access to the PINMMRs**

It is recommended to disable write access to the PINMMRs once the I/O multiplexing configuration is completed. This can be done by:

- writing any other data value to either of the kick registers, or
- restarting the unlock sequence by writing 0x83e70b13 to the kick0 register

NOTE: No Error On Write to Locked PINMMRs

There is no error response on any write accesses to the PINMMRs when write access is disabled. None of the PINMMRs change state due to this write.

4.6.2 Error Conditions

The IOMM generates one error signal that is mapped to the Error Signaling Module's Group 1, channel 37. This error signal is generated under either of the following two conditions:

- Address Error – occurs when there is a read or a write access to an un-implemented memory location within the IOMM register frame.
- Protection Error – occurs when the CPU writes to an IOMM register while not in a privileged mode of operation.

4.7 IOMM Registers

Table 4-8 lists the memory-mapped registers for the IOMM. All register offset addresses not listed in Table 4-8 should be considered as reserved locations and the register contents should not be modified. The address offset is specified from the base address of FFFF EA00h.

Table 4-8. IOMM Registers

| Offset | Acronym | Register Name | Section |
|-----------------|------------------------|---------------------------------------|--------------------------------|
| 0h | REVISION_REG | Revision Register | Section 4.7.1 |
| 20h | ENDIAN_REG | Device Endianness Register | Section 4.7.2 |
| 38h | KICK_REG0 | Kicker Register 0 | Section 4.7.3 |
| 3Ch | KICK_REG1 | Kicker Register 1 | Section 4.7.4 |
| E0h | ERR_RAW_STATUS_REG | Error Raw Status / Set Register | Section 4.7.5 |
| E4h | ERR_ENABLED_STATUS_REG | Error Enabled Status / Clear Register | Section 4.7.6 |
| E8h | ERR_ENABLE_REG | Error Signaling Enable Register | Section 4.7.7 |
| ECh | ERR_ENABLE_CLR_REG | Error Signaling Enable Clear Register | Section 4.7.8 |

4.7.1 REVISION_REG Register (Offset = 0h) [reset = 4E840102h]

REVISION_REG is shown in [Figure 4-6](#) and described in [Table 4-9](#).

This is a read-only register that provides the revision information about the I/O Multiplexing Module (IOMM).

Figure 4-6. REVISION_REG Register

4.7.2 ENDIAN_REG Register (Offset = 20h) [reset = 0h]

ENDIAN_REG is shown in [Figure 4-7](#) and described in [Table 4-10](#).

This is a read-only register that reflects the state of the device endianness.

Figure 4-7. ENDIAN_REG Register

4.7.3 KICK_REG0 Register (Offset = 38h) [reset = 0h]

KICK_REG0 is shown in [Figure 4-8](#) and described in [Table 4-11](#).

This register forms the first part of the unlock sequence for being able to update the I/O multiplexing control registers (PINMMRn).

Figure 4-8. KICK_REG0 Register

|------|-------|------|-------|--|
| 31-0 | KICK0 | R/W | 0h | Kicker 0 Register. The value 83E7 0B13h must be written to KICK0 as part of the process to unlock the CPU write access to the PINMMRn registers. |

4.7.4 KICK_REG1 Register (Offset = 3Ch) [reset = 0h]

KICK_REG1 is shown in [Figure 4-9](#) and described in [Table 4-12](#).

This register forms the second part of the unlock sequence for being able to update the I/O multiplexing control registers (PINMMRn).

Figure 4-9. KICK_REG1 Register

|------|-------|------|-------|--|
| 31-0 | KICK1 | R/W | 0h | Kicker 1 Register. The value 95A4 F1E0h must be written to the KICK1 as part of the process to unlock the CPU write access to the PINMMRn registers. |

4.7.5 ERR_RAW_STATUS_REG Register (Offset = E0h) [reset = 0h]

ERR_RAW_STATUS_REG is shown in [Figure 4-10](#) and described in [Table 4-13](#).

This register shows the status of the error conditions (before enabling) and allows setting the status. The IOMM module error signal is connected to the device's Error Signaling Module (ESM) group1 channel 37. The application can choose to generate an interrupt whenever this ESM channel flag gets set. This interrupt service routine can then read this Error Raw Status Register to determine the actual cause of the error condition. The Error Raw Status register is also writable by the application in order to test the ESM signaling and interrupt generation mechanism.

Figure 4-10. ERR_RAW_STATUS_REG Register

4.7.12 PINMMR_0 to PINMMR_47 Register (Offset = B10h to BCCh) [reset = 1010101h]

PINMMR_0 to PINMMR_47 is shown in [Figure 4-17](#) and described in [Table 4-20](#).

These registers control the multiplexing of the functionality available on each pad as well as some special multiplexing schemes for specific functionalities on the microcontroller. There are 48 such registers PINMMR0 through PINMMR47. Each 8-bit field of a PINMMR register controls the functionality of a single ball/pin. The mapping between the PINMMRx control registers and the functionality selected on a given terminal is defined in .

Figure 4-17. PINMMR_0 to PINMMR_47 Register

| Bit | Field | Type | Reset | Description |
|-------|---------------|------|-------|---|
| 31-24 | PINMMRx_31_24 | R/W | 1h | Each of these byte-fields control the functionality on a given ball/pin. Please refer to Output Multiplexing and Control table for a list of multiplexed signals. This list is sorted by the control register used. |
| 23-16 | PINMMRx_23_16 | R/W | 1h | Each of these byte-fields control the functionality on a given ball/pin. Please refer to Output Multiplexing and Control table for a list of multiplexed signals. This list is sorted by the control register used. |
| 15-8 | PINMMRx_15_8 | R/W | 1h | Each of these byte-fields control the functionality on a given ball/pin. Please refer to Output Multiplexing and Control table for a list of multiplexed signals. This list is sorted by the control register used. |
| 7-0 | PINMMRx_7_0 | R/W | 1h | Each of these byte-fields control the functionality on a given ball/pin. Please refer to Output Multiplexing and Control table for a list of multiplexed signals. This list is sorted by the control register used. |

4.8 Output Multiplexing and Control

The device output terminals are shared between several different functions. The controls for these outputs are listed in [Table 4-21](#). PINMMR35-PINMMR47 are used to control ePWMx, eCAPx, and eQEPx modules, see [Section 4.5](#) and the device-specific data manual.

F021 Flash Module Controller (FMC)

The Flash electrically erasable programmable read-only memory module is a type of nonvolatile memory which has fast read access times and is able to be reprogrammed in the field or in the application. This chapter describes the F021 Flash module controller (FMC).

| Topic | Page |
|--|----------------------------|
| 5.1 Overview | 267 |
| 5.2 Default Flash Configuration | 268 |
| 5.3 SECEDED | 269 |
| 5.4 Memory Map | 273 |
| 5.5 Deliberate ECC Errors for FMC ECC Checking | 276 |
| 5.6 Power On, Power Off, and Reset Considerations | 277 |
| 5.7 Emulation and SIL3 Diagnostic Modes | 277 |
| 5.8 Control Registers | 282 |

5.1 Overview

The F021 Flash is used to provide non-volatile memory for instruction execution or data storage. The Flash can be electrically programmed and erased many times to ease code development.

Refer to the following documents for support in how to initialize and use the on-chip Flash and its API:

- *Initialization of Hercules ARM Cortex-R4F Microcontrollers Application Report* ([SPNA106](#))
- *F021 (Texas Instruments 65nm Flash) Flash API Reference Guide* ([SPNU501](#))

5.1.1 Features

- Read, program and erase with a single 3.3 V supply voltage
- Supports error detection and correction
 - Single Error Correction and Double Error Detection (SECCDED)
 - Error Correction Code (ECC) is evaluated in the CPU for the main Flash bank arrays and in the Flash Wrapper for the EEPROM emulation Flash banks
 - Address bits included in ECC calculation
- Provides different read modes to optimize performance and verify the integrity of Flash contents
- Provides built-in power mode control logic
- Integrated program/erase state machine
 - Simplifies software algorithms
 - Supports simultaneous read access on a bank while performing a write or erase operation on any one of the remaining banks
 - Suspend command allows read access to a sector being programmed/erased
 - Fast erase and program times (for details, see the device-specific data sheet)

For the actual size of the Flash memory for the device, see the device-specific data sheet.

5.1.2 Definition of Terms

Terms used in this document have the following meaning:

- BAGP (Bank Active Grace Period): Time (in HCLK cycles) from the most recent Flash access of a particular bank until that bank enters fallback power mode. This reduces power consumption by the Flash. However, it can also increase access time.
- bw - Normal data space bank data width of a Flash bank. The bw is 128 bits (144 bits including the error correction bits).
- bwe - EEPROM emulation bank is 128 bit wide (144 bits including the error correction bits).
- Charge pump: Voltage generators and associated control (logic, oscillator, and bandgap, for example).
- CSM: Program/erase command state machine
- Fallback power mode: The power mode (active, standby or sleep, depending on which mode is selected) into which a bank or the charge pump falls back each time the active grace period expires.
- Flash bank: A group of Flash sectors which share input/output buffers, data paths, sense amplifiers, and control logic.
- FEE - Flash EEPROM Emulation. Features on the FMC to support using a Flash type memory in place of an EEPROM Flash memory. EEPROM is erasable by the word while this Flash memory is only erasable by the sector. The FEE bank is accessible only through Bus 2 in a special address range and always resides in bank 7.
- Flash module: Flash banks, charge pump, and Flash wrapper.
- Flash wrapper: Power and mode control logic, data path, wait logic, and write/erase state machines.
- FMC - Flash Module Controller.
- Command - A sequence of coded instructions to Flash module to execute a certain task.

- **FSM (Flash State Machine)** - State machine which parses and decodes FSM commands. It executes embedded algorithms and generates control signals to both Flash bank and charge pump during the actual program/erase operation.
- **OTP (one-time programmable)**: A program-only-once Flash sector (cannot be erased)
- **PAGP (Pump Active Grace Period)**: Time (in HCLK cycles) from when the last of the banks have entered fallback power mode until the pump enters a fallback power mode. This can reduce power consumption by the Flash; however, it can also increase access time.
- **Pipeline mode**: The mode in which Flash is read 128 bits (+ 16 bit ECC) at a time, providing higher throughput.
- **Sector**: A contiguous region of Flash memory which must be erased simultaneously.
- **Wide_Word** - the width of the data output from the Flash bank. This is 144 bits wide for main Flash and for the FEE bank.
- **Standard read mode**: The mode assumed when the pipeline mode is disabled. Physically, 128 (+ 16 bit ECC) is read at a time. However, only 32 bits of data is used while the other bits of data are discarded.
- **Read Margin 1 mode**: More stringent read mode designed for early detection of marginally erased bits.
- **Read Margin 0 mode**: More stringent read mode designed for early detection of marginally programmed bits.

5.1.3 F021 Flash Tools

Texas Instruments provides the following tools for F021 Flash:

- [nowECC](#) Generation Tool - to generate the Flash ECC from the Flash data.
- [nowFLASH](#) Programming Tool - to erase/program/verify the device Flash content through JTAG.
- Code Composer Studio - the development environment with integrated Flash programming capabilities.
- F021 Flash API Library - a set of software peripheral functions to program/erase the Flash module. Refer to *F021 Flash API Reference Guide* ([SPNU501](#)) for more information.

5.2 Default Flash Configuration

At power up, the Flash module state exhibits the following properties:

- Wait states are set to 1 data wait state and 0 address wait states
- Pipeline mode is disabled
- The Flash content is protected from modification
- Power modes are set to *Active* (no power savings)
- The boot code must initialize the wait states (including data wait states and address wait states) and the desired pipeline mode by initializing the FRDCNTL register to achieve the optimum system performance. This needs to be done before switching to the final device operating frequency. Refer to *Initialization of Hercules ARM Cortex-R4F Microcontrollers Application Report* ([SPNA106](#)) for more information.

5.3 SECDED

The Flash memory can be protected by Single Error Correction Double Error Detection (SECDED). The main program memory is protected by the SECDED circuit inside of the Cortex-R4 CPU. All OTP and the FEE memory (bank 7) is protected by SECDED logic in the flash wrapper.

5.3.1 SECDED Initialization

Flash error detection and correction is not enabled at reset. To enable SECDED, error correction detection must be enabled in the flash wrapper, the CPU event bus must be enabled and SECDED must be enabled within the CPU. Refer to *Initialization of Hercules ARM Cortex-R4F Microcontrollers Application Report* ([SPNA106](#)) for information on these steps.

The ECC values for all of the ATCM program memory space (flash banks 0 through 6) must be programmed into the flash before SECDED is enabled. This can be done by generating the correct values of the ECC with an external tool such as [nowECC](#) or may be generated by the programming tool. The Cortex-R4 CPU may generate speculative fetches to any location within the ATCM memory space. A speculative fetch to a location with invalid ECC, which is subsequently not used, will not create an abort, but will set the ESM flags for a correctable or uncorrectable error. An uncorrectable error will unconditionally cause the nERROR pin to toggle low. Therefore care must be taken to generate the correct ECC for the entire ATCM space including the holes between sections and any unused or blank flash areas.

The Cortex-R4 CPU does not generate speculative fetches into the address space of bank 7, the EEPROM Emulation flash. It is only necessary to initialize the ECC values of the locations which will be intentionally read by the CPU or other bus masters.

5.3.2 ECC Encoding

Nineteen address lines are also included in the ECC calculation. A failure of a single address line inside of the bank will be treated as an uncorrectable error. The ECC encoding is shown in [Table 5-1](#). Bits 31:0 come from the word at the address ending in 0x0 or 0x8, Bits 63:31 come from the word at the address ending in 0x4 or 0xC.

Table 5-1. ECC Encoding for BE32 Devices

| x | | | | x | | | | x | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |

(1) For Odd parity, XOR a 1 to the row's XOR result. For even Parity, use the row's XOR result directly.

(2) Each ECC[x] bit represents the XOR of all the address and data bits marked with x in the same row.

5.3.3 Syndrome Table: Decode to Bit in Error

The syndrome is a 8 bit value which decodes to the bit in error. The bit in error can be a bit among the 64 data bits, the 19 address bits or a bit among the 8 ECC check bits. A syndrome value of 00000000 indicates there is no error. Any other syndrome combinations not shown in the table are un-correctable multi-bit error. Errors of three or more bits may escape detection. The syndrome decoding is shown in [Table 5-2](#).

Table 5-2. Syndrome Table, Decode to Bit in Error

| | Address Bit Error Position | | | | | | | | | | | | | | | | | | |
|--|----------------------------|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|

5.4 Memory Map

The Flash module contains the program memory, which is mapped starting at location zero, and one Customer OTP sector and one TI OTP sector per bank. The Customer OTP sectors may be programmed by the customer, but cannot be erased. They are typically blank in new parts. The TI OTP sectors are used to contain manufacturing information. They may be read by the customer but can not be programmed or erased. The TI OTP sectors contain settings used by the Flash API to setup the Flash state machine for erase and program operations.

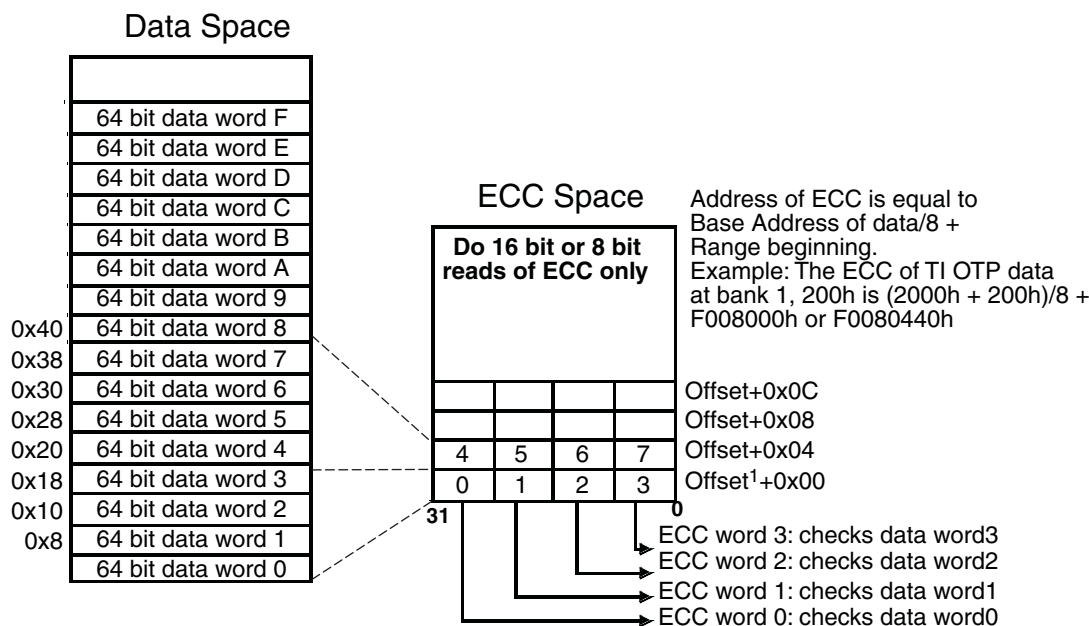

All of these OTP regions are memory-mapped to facilitate ease of access by the CPU. They are memory mapped to an offset starting at F000 0000h in the CPU's memory map.

The RWAIT value is used to define the number of wait states for the program memory flash. The EWAIT value is used to define the number of wait states for the data flash in bank 7. Bank 7 starting at offset F020 0000h is dedicated for data storages such as EEPROM Emulation.

5.4.1 Location of Flash ECC Bits

The flash ECC bits can be read starting at address 0xF0400000. The ECC bits are packed in their memory space as shown in Figure 5-1. The ECC bytes must be read as bytes or halfwords. Reading a single ECC byte with ECC enabled will actually cause 144 bits to be read from the flash, and the ECC bits will be corrected if necessary. Any errors in either of the two double-words accessed will be recorded in the FEDACSTATUS register (main memory) or the EE_STATUS register (bank 7).

Figure 5-1. ECC Byte Mapping

5.4.2 OTP Memory

5.4.2.1 Flash Bank and Sector Sizes

Flash Bank/Sectoring information can be determined from the device-specific datasheet or can be computed by reading locations in the TI OTP and FMC registers.

The number of banks, which banks are available, and the number of sectors for bank 0 can be read from TI OTP location F008 0158h as shown in [Figure 5-2](#) and described in [Table 5-4](#).

Figure 5-2. TI OTP Bank 0 Sector Information

LEGEND: R = Read only

Table 5-4. TI OTP Bank 0 Sector Information Field Descriptions

| Bit | Field | Value | Description |
|-------|----------------|--------|---------------------------------------|
| 31-24 | Reserved | 0 | Reserved. All bits will be read as 0. |
| 23-16 | BX_NUM_Sectors | 1-32 | Number of sectors in this bank. |
| 15 | B7 | 1 | 1 = Bank 7 is present |
| 14 | B6 | 0 | 0 = Bank 6 is not present |
| 13 | B5 | 0 | 0 = Bank 5 is not present |
| 12 | B4 | 0 | 0 = Bank 4 is not present |
| 11 | B3 | 0 | 0 = Bank 3 is not present |
| 10 | B2 | 0 | 0 = Bank 2 is not present |
| 9 | B1 | 1 | 1 = Bank 1 is present |
| 8 | B0 | 1 | 1 = Bank 0 is present |
| 7-0 | NUM_Banks | 2 or 3 | Number of banks on this part. |

The bank sector information is repeated once for each bank in the device. The number of sectors is unique for each bank. The number of banks and which banks are implemented is repeated in each location. Use the TI OTP information for bank 0 to determine which banks are in the device, and then read the number of sectors for each bank using the TI OTP locations shown in [Table 5-5](#).

Table 5-5. TI OTP Sector Information Address

| Bank | TI OTP Address |
|------|----------------|
| 0 | F008 0158h |
| 1 | F008 2158h |
| 2 | F008 4158h |
| 3 | F008 6158h |
| 4 | F008 8158h |
| 5 | F008 A158h |
| 6 | F008 C158h |
| 7 | F008 E158h |

5.4.2.2 Package and Memory Size

Package and memory size information can be determined from the device-specific datasheet, or can be computed by reading locations in the TI OTP Bank 0 registers.

The package and memory size can be read from TI OTP location F008 015Ch as shown in [Figure 5-3](#) and described in [Table 5-6](#).

Figure 5-3. TI OTP Bank 0 Package and Memory Size Information (F008 015Ch)

5.4.2.4 Part Number Symbolization

Device part number symbolization information can be determined from the device-specific datasheet or can be computed by reading locations in the TI OTP bank 0 registers.

For example the device part number symbolization "TMS570LS3137CPGEQQ1" can be read from TI OTP bank 0 location F008 01E0h through F008 01FFh as shown in [Figure 5-5](#).

Figure 5-5. TI OTP Bank 0 Symbolization Information (F008 01E0h-F008 01FFh)

| | | | | | | | | | | | | | | | |

5.5 Deliberate ECC Errors for FMC ECC Checking

Deliberate single bit and double bit errors have been placed in the OTP for checking the FMC ECC functionality. Any portion of the 64 bits in TI OTP bank 0 location F008 03F0h through F008 03F7h as shown in [Figure 5-6](#) will generate a single bit error. Any portion of the 64 bits in TI OTP bank 0 location F008 03F8h through F008 03FFh as shown in [Figure 5-6](#) will generate a double bit error.

Figure 5-6. TI OTP Bank 0 Deliberate ECC Error Information (F008 03F0h-F008 03FFh)

5.6 Power On, Power Off, and Reset Considerations

5.6.1 Error Checking at Power On

As the device is coming out of the device reset sequence, the flash wrapper reads two configuration words from the TI OTP section of bank 0, the hardware configuration word at address 0xF0080140, and then the AJSM visible password at address 0xF0000000. During these reads ECC is enabled. Single bit errors are corrected and generate an ESM group 1 channel 6 error event. The first failing address will be latched in the FCOR_ERR_ADD register along with the bit position in FCOR_ERR_POS register and the FEDACSTATUS register flags will be updated to indicate the type of error. Uncorrectable errors will generate an ESM group 3 channel 7 error event, the ERROR pin will be activated, the first failing address will be latched in the FUNC_ERR_ADD register and the FEDACSTATUS register flags will be updated to indicate the type of error.

5.6.2 Flash Integrity when Reset while Programming or Erasing

If a device is reset while programming, then the bits being programmed when reset is asserted are indeterminate, however the other bits in the flash are not disturbed. Likewise, If the device is reset while being erased, the sector or sectors being erased will have indeterminate bits, however the other sectors in the same bank, and the other banks will not be disturbed.

5.6.3 Flash Integrity at Power Off

If power is lost during a programming or erase operation, a power-on reset must be asserted before the core supply voltage drops below specification. The PORRST pin has a glitch filter which means that the PORRST pin must be asserted low $t_{(nPORRST)}$ (2us) before the core supply drops below V_{CC_MIN} (1.14V). If this requirement is met, then the bits being programmed when PORRST goes low are indeterminate, however the other bits in the flash are not disturbed. Likewise, if this requirement is met, and PORRST is asserted while erasing, the sector or sectors being erased will have indeterminate bits; however, the other sectors in the same bank, and the other banks will not be disturbed.

5.7 Emulation and SIL3 Diagnostic Modes

5.7.1 System Emulation

During emulation when SUSPEND signal is high, the data read from memory is still passed to SECDED for correction if ECC_ENABLE is active. If a correctable error is detected then it is corrected but error event is not generated and error occurrence counter is not incremented if in profiling mode. If a double error is detected then the raw data is returned without generating double error signal.

The SUSPEND signal can be disabled by using the SUSP_IGNORE bit in FEDACCTRL1 register. The SUSPEND signal should not be confused with the suspend_now operation for the FSM.

5.7.2 Diagnostic Mode

Flash wrapper can be put in diagnostic mode to verify various logic. There are multiple diagnostic modes supported by the wrapper. A specific diagnostic mode is selected via DIAG_MODE control bits.

Diagnostic mode is only enabled via a 4-bit key stored in DIAG_EN_KEY. Only DIAG_EN_KEY=0101 will enable any diagnostic mode and all diagnostic modes use the DIAG_TRIG to initiate the action.

All tests will run from any pipeline mode. Some of the diagnostic modes can corrupt the flash data access, and generate errors as part of the test. Running in non-pipeline may minimize some of these conditions.

For all modes it is best to follow this sequence.

1. Write 0101 to the DIAG_EN_KEY register and set the desired DIAG_MODE. This will block many UERR sources.
2. Set any data registers needed for this mode.
3. Write a one to the DIAG_TRIG to initiate the action and allow UERRs to happen for one cycle.
4. Write 1010 to DIAG_EN_KEY to exit the diagnostic modes.

When the CONF_TYPE is 5 then the ECC logic is in the CPU and most of diagnostic modes are removed. Some because the logic they test no longer exists and the rest because the path is validated via the ECC path to the CPU.

Table 5-8. DIAG_MODE Encoding

| Mode | DIAG_MODE Bits | | | Description |
|------|----------------|---|---|---|
| 0 | 0 | 0 | 0 | Diagnostic mode is disabled. Same as DIAG_EN_KEY not equal to 5h. |
| 1 | 0 | 0 | 1 | ECC Data correction test mode. |
| 2 | 0 | 1 | 0 | ECC Syndrome reporting test mode. |
| 3 | 0 | 1 | 1 | ECC Malfunction test mode 1 (same data mode) |
| 4 | 1 | 0 | 0 | ECC Malfunction test mode 2 (inverted data mode) |
| 5 | 1 | 0 | 1 | Address Tag Register test mode |
| 6 | 1 | 1 | 0 | Reserved |
| 7 | 1 | 1 | 1 | ECC Data Correction |

5.7.2.1 ECC Data Correction Mode 1

This diagnostic mode can be enabled while ECC logic is also enabled for normal bank read. The flash wrapper will arbitrate the usage of the ECC logic if a conflict occurs between a normal bank read and diagnostic checking.

When in diagnostic data correction mode, FEMU_xxxx registers contain the 64-bit EEPROM emulation data register, the 19-bit emulation address register and the 8-bit emulation check-bit register. These values are used to enter diagnostic data to exercise the SECDED logic. The user can apply a value with an error in any bit location. When the DIAG_TRIG is set, the SECDED calculation is done and the corrected values are saved back into the same FEMU_xxxx registers. The error position register is also updated to indicate the bit position in error. Either ERR_ONE_FLG or ERR_ZERO_FLG bit is set when a correctable error is detected. The D_COR_ERR bit will be also be set in FEDACSTATUS. For uncorrectable error the double/multi bit error status bit ECC_MUL_ERR is set as well as the D_UNC_ERR bit in the same register. Status bits should be cleared by the user before applying a new diagnostic data.

It takes multiple CPU transactions to preload the registers with diagnostic values. During this time, the result of the diagnostic logic such as comparator can change. User should apply a trigger by setting DIAG_TRIG bit to 1 as a qualifier after all registers are loaded with intended values. The DIAG_TRIG serves to validate the diagnostic result. Only when DIAG_TRIG is high and a failing result in the diagnostic logic will update the corresponding status flag and the position register.

5.7.2.2 ECC Syndrome Report Mode 2: DIAG_MODE = 2

When in diagnostic syndrome reporting mode, the resulting syndrome calculated by SECDED is captured into the ECC check-bit register FEMU_ECC. The syndrome can be read by the user and compare with a known syndrome value. Diagnostic data in FEMU_DxSW and FEMU_ADDR is not corrected and the error position register is not updated. The FEDACSTATUS error bits are not updated during this mode. See .

For devices with ECC_IN_CPU (CONF_TYPE = 5), the resulting FEMU_ECC value will represent the 32-bit byte swapped values. Here, bytes 7654_3210 are rearranged to 4567_0123. For instance, if the syndrome shows an error in data bit 33, it would really be an error in EMU_DMW bit 57. You can also XOR the data bit position with "011000". (21h XOR 18h => 39h)

NOTE: The user should pre-load the registers with the test values with DIAG_TRIG = 0. After all test values are written, the DIAG_TRIG should then be set high to validate the diagnostic result.

5.7.2.3 ECC Malfunction Test Mode 3: DIAG_MODE = 3

There are three inputs to the malfunction detection logic: the resulting syndrome, the original uncorrected data, and the final corrected data.

In normal function, the malfunction detection logic will detect an error if the syndrome is 0 and if the data before the correction and the data after the correction is not equal; or if the syndrome is not 0 and if the data before the correction and data after the correction is equal to each other. During diagnostic mode 3 or 4, user supplied values are sent to the malfunction logic. No functional checking is done by the ecc_malfunction logic while the mode is 3 or 4.

Diagnostic mode 3 is also known as “same data” mode. A diagnostic value can be stored in the ECC checkbit register. The value stored in the 64-bit Raw data register will be supplied to the two inputs of the malfunction comparator logic. If a non-zero value is stored in the Raw ECC checkbit register (FRAW_ECC), then the malfunction logic should detect it as an error. The DIAG_TRIG is set to initiate this mode.

5.7.2.4 ECC Malfunction Test Mode 4: DIAG_MODE = 4

Diagnostic mode 4 is also known as “inverted data” mode. A diagnostic value can be stored in the ECC checkbit register. A value stored in the 64-bit Raw data register and its bit-wise inverted counterpart will be supplied to the two inputs of the malfunction comparator logic. If a zero value is stored in the Raw ECC checkbit register (FRAW_ECC), then the malfunction logic should detect it as an error.

Set the ECC_SEL bits before entering mode 4 or enter mode 4 from a nonmode 4 and set the ECC_SEL bits at the same time.

5.7.2.5 Address Tag Register Test Mode 5: DIAG_MODE = 5

There are four sets of address tag registers. Each set consists of a primary and a duplicate address tag registers. Normally, these registers stores the recently issued CPU addresses during pipeline mode. To detect errors in these registers, the primary and duplicate address tag registers are continuously compared to each other if the buffer is valid. If they are different then an address tag register error event is generated.

These registers are memory mapped. All primary address tag registers are memory mapped to one address and likewise, all duplicate tag registers are mapped to another single address. During diagnostic mode, each individual set can be selected via the 2-bit DIAG_BUF_SEL (Diagnostic buffer select) register. User supplied values can be written into the selected set during a diagnostic mode. If different values are written into the primary and the duplicate address tag registers then the ADD_TAG_ERR (Address Tag Error) register will be set. This diagnostic mode uses the FRAW_DATA register to supply the alternate address when DIAG_TRIG is set. The FUNC_ERR_ADD will not contain useful information during Diag mode 5. It will also trigger the normal uncorrectable register freeze.

All address tags and buffer valid bits will be set to zero when leaving diag_mode 5. Going to mode 5 and back out clears the pipeline buffers and is useful for other test modes also. No functional checking is done by the address tag logic while the mode is 5.

NOTE: The user should pre-load the registers with the test values with DIAG_TRIG = 0. After all test values are written, the DIAG_TRIG should then be set high to validate the diagnostic result.

5.7.2.6 ECC Data Correction Diagnostic Mode 7: DIAG_MODE = 7

Testing the error correction and ECC logic in the CPU involves corrupting the ECC value returned to the CPU. By inverting one or more bits of the ECC, the CPU will detect errors in a selected data or ECC bit, or in any possible value returned by the ECC.

To set an error for a particular bit use the syndrome, see [Table 5-3](#). For instance, if you want to corrupt data bit 62 then put the value 70h into the test register.

The method uses the DATA_INV_PAR value in the FPAR_OVR register to alter the ECC during a slave access cycle. The value in the DATA_INV_PAR register will be XORed with the current ECC to give a bad ECC value to the CPU. This only will occur when the DIAG_MODE is 7, the PAR_OVR_KEY is 5, the DIAG_EN_KEY in the FDIAGCTRL register is 5 and the access is a slave cycle.

This mode can set the FEDACSTATUS status error bits ECC_MUL_ERR or ERR_ZERO_FLG, but it will not set D_UNC_ERR nor D_COR_ERR.

The sequence to do this test would be:

1. Make sure the true DMA module is off.
2. Put 5h into PAR_OVR_KEY and 5h into DAT_INV_PAR fields (00005Axxh) of the FPAR_OVR register (0x7C).
3. Put the desired value in DAT_INV_PAR field of FPAR_OVR register.
4. Put 7h in DIAG_MODE, and 5h in DIAG_EN_KEY of the FDIAGCTRL register (0x6C).
5. Read desired address from the mirrored flash location. Mirrored flash starts at address 0x20000000.
6. Put 0 in DIAG_MODE or Ah in one of the key fields to turn off this test.
7. Check error registers for ECC errors. (0x14, 0x1C, 0x20).
8. Repeat as necessary to test out the ECC.
9. Put 0 in DIAG_MODE and Ah in both of the key fields to completely disable this test at the end of the test.
10. Write 5400h to FPAR_OVR to clear DAT_INV_PAR and put 2h into PAR_OVR_KEY.

5.7.3 Diagnostic Mode Summary

The following tables give a summary of the input registers needed for each mode, the possible registers that can change and the possible error bits in FEDACSTATUS that may set.

Table 5-9. Bus1 Diagnostic Mode Summary

| DIAG MODE | Name | Inputs | Possible Outputs | Possible Error Bits Set | Notes |

5.7.4 Read Margin

When the bits are programmed or erased, they are checked against a program_verify or erase_verify reference level that is far away from the normal read reference point. Over time, bit levels may drift toward the normal read point and if it is too much then a bit will read the wrong value. To counteract this, the bits can be read using different read_margin reference points to give an early detection of the problem. The bits can then be either re-programmed (most common) or the sector can be erased and reprogrammed.

5.8 Control Registers

This section details the Flash module registers, summarized in [Table 5-12](#). A detailed description of each register and its bits is also provided.

The Flash module control registers can only be read and/or written by the CPU while in privileged mode. Each register begins on a word boundary. All registers are 32-bit, 16-bit and 8-bit accessible. The start address of the Flash module is FFF8 7000h.

Table 5-12. Flash Control Registers

| Address | Acronym | Register Description | Section |
|------------|----------------|--|--------------------------------|

5.8.1 Flash Option Control Register (FRDCNTL)

FRDCNTL supports pipeline mode. This register controls flash timings for the main flash banks. For the equivalent register that controls flash timings for the EEPROM Emulation flash bank (bank 7), see [Section 5.8.34](#).

Figure 5-7. Flash Option Control Register (FRDCNTL) [offset = 00h]

LEGEND: R/W = Read/Write; R = Read only; WP=Write in Privilege Mode; -n = value after reset

Table 5-13. Flash Option Control Register (FRDCNTL) Field Descriptions

| Bit | Field | Value | Description |
|-------|----------|--------|---|
| 31-12 | Reserved | 0 | Read returns 0. Writes have no effect. |
| 11-8 | RWAIT | 0-Fh | Random/data Read Wait State The random read wait state bits indicate how many wait states are added to a flash read access. In Pipeline mode there is always one wait state even when RWAIT is set to 0. Note: The required wait states for each HCLK frequency can be found in the device-specific data sheet. |
| 7-5 | Reserved | 0 | Read returns 0. Writes have no effect. |
| 4 | ASWSTEN | 0 1 | Address Setup Wait State Enable Address Setup Wait State is disabled. Address Setup Wait State is enabled. Address is latched one cycle before decoding to determine pipeline hit or miss. Address Setup Wait State is only available in pipeline mode. Note: The required address wait state for each HCLK frequency can be found in the device-specific data sheet. |
| 3-1 | Reserved | 0 | Read returns 0. Writes have no effect. |
| 0 | ENPIPE | 0 1 | Enable Pipeline Mode Pipeline mode is disabled. Pipeline mode is enabled. |

5.8.2 Flash Error Detection and Correction Control Register 1 (FEDACCTRL1)

This register controls ECC event detection for the main flash banks. For the equivalent register that controls ECC event detection for the EEPROM Emulation flash bank (bank 7), see [Section 5.8.35](#).

Figure 5-8. Flash Error Detection and Correction Control Register 1 (FEDACCTRL1) [offset = 08h]

| | | | | | | | | | | | | | | | | | | |
|----------|----|--|--|--|--|--|--|--|--|----------|----|--------|----|--------|---|----|----|-----------|
| 31 | | | | | | | | | | | | | | | | 25 | 24 | |
| Reserved | | | | | | | | | | | | | | | | | | SUSP_IGNR |
| R-0 | | | | | | | | | | | | | | | | | | R/WP-0 |
| 23 | 20 | | | | | | | | | | 19 | | | | | 16 | | |

| R-0 | | | | | | | | | | R/WP-5h | | | | | | | | |

LEGEND: R/W = Read/Write; R = Read only; WP=Write in Privilege Mode; -n = value after reset

Table 5-14. Flash Error Detection and Correction Control Register 1 (FEDACCTRL1) Field Descriptions

| Bit | Field | Value | Description |
|-------|-----------|------------------|---|
| 31-25 | Reserved | 0 | Read returns 0. Writes have no effect. |
| 24 | SUSP_IGNR | 0 | Suspend Ignore. In emulation mode, for example, viewing memory in the debugger's window, the CPU suspend signal is set. This bit determines whether the CPU suspend signal is ignored by the flash module. CPU suspend signal blocks error bits setting and un-freezing. The flash module blocks all errors from setting the error bits in emulation mode and blocks the un-freezing of the bits and registers by reading the FUNC_ERR_ADD register. |
| | | 1 | CPU suspend has no effect on error bit setting and un-freezing. The flash module ignores the CPU suspend signal and allows the error bits to set even in emulation mode. It also allows the flash module to un-freeze the error bits and other registers by reading the FUNC_ERR_ADD register even in emulation mode. |
| 23-20 | Reserved | 0 | Read returns 0. Writes have no effect. |
| 19-16 | EDACMODE | 5h | Error Correction Mode. Single bit errors during reads from OTP, ECC and the mirrored space (starting at 0x20000000) of banks 0 through 6, will be treated as uncorrectable errors by the flash wrapper. The wrapper will assert an ESM group 3 error on channel 7 and the ERROR pin will be activated. No abort will be taken by the CPU. |
| | | All Other Values | Single bit errors during reads from OTP, ECC and the mirrored space (starting at 0x20000000) of banks 0 through 6, will be treated as correctable errors by the flash wrapper. The wrapper will assert an ESM group 1 error on channel 6. The single bit error will be corrected. Note: This mode does not affect reads from the main program flash starting at address zero. Note: Reading ECC bits will generate an ECC error based on the contents of the 8 ECC bits and the 64 data bits they protect |
| 15-11 | Reserved | 0 | Read returns 0. Writes have no effect. |

**Table 5-14. Flash Error Detection and Correction Control Register 1 (FEDACCTRL1)
Field Descriptions (continued)**

| Bit | Field | Value | Description |
|-----|----------|----------------------------|---|
| 10 | EOFEN | 0 1 | <p>Event on Ones Fail Enable</p> <p>No ESM error event is generated on a single bit error where a one reads as a zero when reading from the OTP or ECC memory locations.</p> <p>An ESM error event is generated on a single bit error where a one reads as a zero when reading from the OTP or ECC memory locations.</p> <p>Note: When either the EOFEN or the EZFEN bit is set, an error event will be generated on ESM group 1 channel 6 when any correctable error is generated by reading the main memory</p> |
| 9 | EZFEN | 0 1 | <p>Event on Zeros Fail Enable</p> <p>No ESM error event is generated on a single bit error where a zero reads as a one when reading from the OTP or ECC memory locations.</p> <p>An ESM error event is generated on a single bit error where a zero reads as a one when reading from the OTP or ECC memory locations.</p> <p>Note: When either the EOFEN or the EZFEN bit is set, an error event will be generated on ESM group 1 channel 6 when any correctable error is generated by reading the main memory</p> |
| 8 | EPEN | 0 1 | <p>Error Profiling Enable.</p> <p>Error profiling is disabled.</p> <p>Error profiling is enabled.</p> <p>The correctable error event is generated (ESM group 1 channel 6) when the number of CPU accesses of correctable bit errors detected and corrected has reached the threshold value defined in the FEDACCTRL2 register.</p> |
| 7-4 | Reserved | 0 | Read returns 0. Writes have no effect. |
| 3-0 | EDACEN | 5h All Other Values | <p>Error Detection and Correction Enable</p> <p>CPU single and double error event signals are blocked.</p> <p>Note: It is recommended to enable ECC in the flash wrapper by writing "1010" to these bits before enabling ECC in the CPU. If ECC is enabled in the CPU, but not in the wrapper, the CPU will still check and correct single bit ECC errors, and generate aborts on uncorrectable errors for the main flash. However, the generation of ESM events, the capture of failing addresses and the detections and correction of errors in the OTP will be prevented.</p> <p>Error Detection and Correction events are captured and sent to the ESM</p> |

5.8.3 Flash Error Correction and Correction Control Register 2 (FEDACCTRL2)

This register applies to ECC event detection for the main flash banks. For the equivalent register which applies to the EEPROM Emulation flash bank (bank 7), see [Section 5.8.36](#).

Figure 5-9. Flash Error Correction and Correction Control Register 2 (FEDACCTRL2)
[offset = 0Ch]

| | | |
|--------|---------------|----|
| 31 | Reserved | 16 |
| R-0 | | |
| 15 | SEC_THRESHOLD | 0 |
| R/WP-0 | | |

LEGEND: R/W = Read/Write; R = Read only; WP=Write in Privilege Mode; -n = value after reset

Table 5-15. Flash Error Correction Control and Correction Register 2 (FEDACCTRL2)
Field Descriptions

| Bit | Field | Value | Description |
|-------|---------------|-------|--|
| 31-16 | Reserved | 0 | Read returns 0. Writes have no effect. |
| 15-0 | SEC_THRESHOLD | | Single Error Correction Threshold When error profiling is enabled, this register contains the threshold value for the SEC (single error correction) occurrences before a correctable error event is generated (ESM group 1, channel 6). A threshold of zero disables the threshold so that it does not generate an event. |

5.8.4 Flash Correctable Error Count Register (FCOR_ERR_CNT)

This register applies to the main flash banks. For the equivalent register which applies to the EEPROM Emulation flash bank (bank 7), see [Section 5.8.37](#).

Figure 5-10. Flash Correctable Error Count Register (FCOR_ERR_CNT) [offset = 10h]

| | | |
|--------|----------|----|
| 31 | Reserved | 16 |
| R-0 | | |
| 15 | FERRCNT | 0 |
| R/WP-0 | | |

LEGEND: R/W = Read/Write; R = Read only; WP=Write in Privilege Mode; -n = value after reset

Table 5-16. Flash Correctable Error Count Register (FCOR_ERR_CNT) Field Descriptions

| Bit | Field | Value | Description |
|-------|----------|-------|--|
| 31-16 | Reserved | 0 | Read returns 0. Writes have no effect. |
| 15-0 | FERRCNT | | Single Error Correction Count This register contains the number of SEC (single error correction) occurrences. Writing any value to this register resets the count value to zero. The counter resets to zero when it increments to be equal to the single error correction threshold. This register only increments when profiling mode is enabled. This register is not affected by the EOFEN or EZEFEEN error control bits in the FEDACCTRL1 register. |

5.8.5 Flash Correctable Error Address Register (FCOR_ERR_ADD)

This register applies to the main flash banks. For the equivalent register which applies to the EEPROM Emulation flash bank (bank 7), see [Section 5.8.38](#).

The error address is captured during errors when either EOFEN or EZFEN enable bit is set. During error profiling mode when only EPEN is set, the error address is not captured if a correctable error is detected. This register is frozen while either the ERR_ZERO_FLG or the ERR_ONE_FLG bit is set in the FEDACSTATUS register.

During emulation mode, this address is frozen even when read. By setting the SUSP_IGNORE bit (see [Table 5-14](#)), this register can be un-frozen in emulation mode.

This register is not changed with the reset signal and contains unknown data at powerup.

Figure 5-11. Flash Correctable Error Address Register (FCOR_ERR_ADD) [offset = 14h]

LEGEND: R = Read only; -n = value after reset; -u = unchanged value on internal reset, cleared on power up

Table 5-17. Flash Correctable Error Address Register (FCOR_ERR_ADD) Field Descriptions

| Bit | Field | Value | Description |
|------|-------------|--------------|--|
| 31-3 | COR_ERR_ADD | 0-1FFF FFFFh | Correctable Error Address COR_ERR_ADD records the CPU logical address of which a correctable error is detected by the ECC logic. This error address is frozen from begin updated until it is read by the CPU. Additional error are blocked until this register is read. |
| 2-0 | B_OFF | 0-7h | Byte Offset Since ECC is checked on 64 bit data, when checking main memory or OTP, the address captured is aligned to a 64-bit boundary with address bits[2:0] equal to 0. When reading from the ECC bytes, these bits will indicate the failing address of the ECC location associated with the failure. When reading an ECC byte, the ECC is checked against the 64 data bits they protect. |

5.8.6 Flash Correctable Error Position Register (FCOR_ERR_POS)

This register applies to the main flash banks. For the equivalent register which applies to the EEPROM Emulation flash bank (bank 7), see [Section 5.8.39](#).

Note: The bit error position is only detected during reads of the OTP, the mirrored flash image or the ECC bytes. Single bit errors corrected during reads of the main memory will only capture the failing address, but not the bit position. The bit position is captured during errors when either EOFEN or EZFEN enable bit is set. During error profiling mode when only EPEN is set, the bit position is not captured if a correctable error is detected. This register is frozen while either the ERR_ZERO_FLG or the ERR_ONE_FLG bit is set in the FEDACSTATUS register.

During emulation mode, this address is frozen even when read. By setting the SUSP_IGNR bit, this register can be un-frozen in emulation mode.

This register is not changed with the reset signal and contains unknown data at powerup.

Figure 5-12. Flash Correctable Error Position Register (FCOR_ERR_POS) [offset = 18h]

LEGEND: R = Read only; -n = value after reset; -u = unchanged value on internal reset, cleared on power up

Table 5-18. Flash Correctable Error Position Register (FCOR_ERR_POS) Field Descriptions

| Bit | Field | Value | Description |
|-------|----------|--------|---|
| 31-10 | Reserved | 0 | Read returns 0. Writes have no effect. |
| 9 | BUS2 | 0 1 | Bus 2 Error The error was in the main flash The error was from an OTP read |
| 8 | TYPE | 0 1 | ErrorType The error was one of the 64 data bits The error was one of the 8 check bits |
| 7-0 | ERR_POS | | The bit address of the single bit error |

5.8.7 Flash Error Detection and Correction Status Register (FEDACSTATUS)

This register applies to the main flash banks. For the equivalent register which applies to the EEPROM Emulation flash bank (bank 7), see [Section 5.8.40](#).

All these error status bits can be cleared by writing a one to the bit. Writing a zero has no effect.

The correctable errors in bits 2:0, and FSM_DONE bit 24, must be cleared before the end of their error event service routine or else the error event will re-issue.

Table 5-19. Flash Error Detection and Correction Status Register (FEDACSTATUS)
Field Descriptions

| Bit | Field | Value | Description |
|-------|----------------|--------|--|
| 31-26 | Reserved | 0 | Read returns 0. Writes have no effect. |
| 25 | Reserved | 0 | Reserved |
| 24 | FSM_DONE | | Flash State Machine Done This bit is set to 1 when the flash state machine completes a program or erase operation. This bit will generate an interrupt on VIM channel 61 if the FSM_EVT_EN bit of the FSM_ST_MACHINE register is set. This bit must be cleared by writing a 1 to it in the interrupt routine to clear the interrupt request. |
| 23-20 | Reserved | 0 | Read returns 0. Writes have no effect. |
| 19 | COMB2_MAL_G | 0 1 | Bus 2 Compare Malfunction Flag. 0 Compare Malfunction detected on the Bus2 SECEDED in diagnostic mode 4 or not in diagnostic mode 1 Compare Malfunction not detected on the Bus2 SECEDED or entered diagnostic mode 4 This bit becomes one when entering diagnostic mode 4, with DIAG_ECC_SEL field set to 0 or 1, and will be cleared if diagnostic mode 4 triggers an error. This bit will reset to zero and will be zero outside of diagnostic mode 4. Writing a one will set this bit to 1 only in diagnostic mode 4 otherwise writes have no effect. |
| 18 | ECC_B2_MAL_ERR | 0 1 | Bus 2 ECC Malfunction Error Flag 0 SECEDED malfunction is not detected on Bus2 1 SECEDED malfunction is detected on Bus2 |

**Table 5-19. Flash Error Detection and Correction Status Register (FEDACSTATUS)
Field Descriptions (continued)**

| Bit | Field | Value | Description |
|-------|-------------|--------|---|
| 17 | B2_UNC_ERR | 0 1 | Bus 2 uncorrectable error No bus 2 uncorrectable errors were detected A bus 2 uncorrectable error was detected Two or more bits in the data, or ECC field; or a single bit error in the address field have been found in error. Address bit errors are considered an uncorrectable error. The FUNC_ERR_ADD register should contain the Bus2 error location. This error will generate an ESM group 3 channel 7 event. |
| 16 | B2_COR_ERR | 0 1 | Bus 2 Correctable Error No bus2 correctable error was detected A bus 2 correctable error was detected One bit in the data, or ECC field has been found in error. Either the ERR_ONE_FLAG or ERR_ZERO_FLAG should be set in this register along with this bit. The FCOR_ERR_ADD register should contain the error address, and the FCOR_ERR_POS register should contain the failing bit position. This error will generate an ESM group 1 channel 6 event. |
| 15-13 | Reserved | 0 | Read returns 0. Writes have no effect. |
| 12 | D_UNC_ERR | | Diagnostic Uncorrectable Error This bit sets when diagnostic mode 1 discovers a multi-bit error using the ECC. This means two or more bits in the data, address or ECC field have been found in error. The ECC is capable of correcting a single-bit error and this would show up in the D_COR_ERR bit. The ECC can always detect two bit errors. Three or more bit errors may escape detection with the ECC. This bit also may set during other uncorrectable errors and during the diagnostic mode like address tag errors and ECC malfunctions. |
| 11 | ADD_TAG_ERR | 0 1 | Address Tag Register Error Flag Address Tag Register Error not detected Address Tag Register Error detected. This bit is set if the primary address tag has a hit but the duplicate address tag does not match the primary address tag. This bit is functional only when pipeline mode is enabled. This error will create an ESM group 3 channel 7 event. |
| 10 | ADD_PAR_ERR | 0 1 | Address Parity Error Flag No address parity error was detected. A parity error was detected on the incoming address bus. The full 32 bit address will be stored in FUNC_ERR_ADD register. This error will create an ESM group 2 channel 4 event. |
| 9 | Reserved | 0 | Read returns 0. Writes have no effect. |
| 8 | B1_UNC_ERR | 0 1 | Bus 1 Uncorrectable Error Flag No Bus 1 uncorrectable errors were detected A bus 1 uncorrectable error was detected Two or more bits in the data, or ECC field; or a single bit error in the address field have been found in error. Address bit errors are considered an uncorrectable error. The FUNC_ERR_ADD register will contain the Bus1 error location. This error will generate an ESM group 3 channel 7 event. |
| 7-4 | Reserved | 0 | Read returns 0. Writes have no effect. |
| 3 | D_COR_ERR | | Diagnostic Correctable Error Status Flag This bit sets when diagnostic mode 1 discovers a single-bit correctable error using the ECC. Multi-bit errors are flagged using the D_UNC_ERR bit. The uncorrectable error address must be unfrozen in order to set this bit. |

**Table 5-19. Flash Error Detection and Correction Status Register (FEDACSTATUS)
Field Descriptions (continued)**

| Bit | Field | Value | Description |
|-----|--------------|-------|---|
| 2 | ERR_ONE_FLG | | Error on One Fail Status Flag |
| | | 0 | No correctable error where a one read as a zero on bus 2 |
| | | 1 | A correctable error occurred on bus 2 where a one read as a zero This bit is set if the EOFEN (Error on One Fail Enable) bit is set then, and one bit in the data, or ECC field which should have been read as a one, read as a zero. During the read the bit is corrected to a one. The FCOR_ERR_ADD register will contain the bus 2 error address, and the FCOR_ERR_POS register will contain the failing bit position. This error will generate an ESM group 1 channel 6 event. When this bit is set, the B2_CORR_ERR bit will also be set. This error will generate an ESM group 1 channel 6 event. |
| 1 | ERR_ZERO_FLG | | Error on Zero Fail Status Flag |
| | | 0 | No correctable errors on bus1 nor any correctable errors on bus 2 where a zero was read as a one |
| | | 1 | A correctable error occurred on bus 1, or a correctable error occurred on bus 2 where a zero was read as a one This bit is set if the EZFEN (Error on Zero Fail Enable) bit is set and a correctable error is detected on bus 2 where a zero is read as a one and corrected to be a zero, or if either the EZFEN or the EOFEN bits are set and any single bit error is detected and corrected on bus 1. The FCOR_ERR_ADD register will contain the error address. If the error was on bus 2, then the B2_CORR_ERR bit will also be set and the FCOR_ERR_POS register will contain the failing bit position. The FCOR_ERR_POS register will not indicate the failing bit position for a bus 1 error. This error will generate an ESM group 1 channel 6 event. |
| 0 | ERR_PRF_FLG | | Error Profiling Status Flag |
| | | 0 | Error profiling is not enabled, or the number of correctable errors has not reached the threshold programmed into the SEC_THRESHOLD register |
| | | 1 | Error profiling is enabled and the number of correctable errors has reached the threshold programmed into the SEC_THRESHOLD register |

5.8.8 Flash Un-Correctable Error Address Register (FUNC_ERR_ADD)

This register applies to ECC event detection for the main flash banks. For the equivalent register which applies to the EEPROM Emulation flash bank (bank 7), see [Section 5.8.41](#).

During emulation mode, this address is frozen even when read. By setting the SUSP_IGNR bit, (see [Table 5-14](#)) this register can be un-frozen in emulation mode.

This register is not changed with the reset signal and contains unknown data at powerup.

Figure 5-14. Flash Un-Correctable Error Address Register (FUNC_ERR_ADD) [offset = 20h]

LEGEND: R = Read only; -n = value after reset; -u = unchanged value on internal reset, cleared on power up

Table 5-20. Flash Un-Correctable Error Address Register (FUNC_ERR_ADD) Field Descriptions

| Bit | Field | Value | Description |
|------|-------------|--------------|--|
| 31-3 | UNC_ERR_ADD | 0-1FFF FFFFh | Un-correctable Error Address UNC_ERR_ADD records the CPU logical address of which an un-correctable error is detected by the ECC logic in the CPU. The UNC_ERR_ADD also captures the error address when a address bus parity mismatch is detected. This error address is frozen from begin updated until it is read by the CPU. Additional error are blocked until this register is read. This register captures the full 32 bit incoming address when there is a bus parity error. It only captures address of 22:3 for multiple bit ECC errors. Address parity errors take priority over other errors that happen in the same cycle. |
| 2-0 | B_OFF | 0-7h | Byte offset Since ECC is checked on 64 bit data, when checking main memory or OTP, the address captured is aligned to a 64-bit boundary with address bits[2:0] equal to 0. When reading from the ECC bytes, these bits will indicate the failing address of the ECC location associated with the failure. When reading an ECC byte, the ECC is checked against the 64 data bits they protect. |

5.8.9 Flash Error Detection and Correction Sector Disable Register (FEDACSDIS)

This register is used to disable the SECDED function for one or two sectors from the EEPROM Emulation flash (bank 7). An additional two sectors can have SECDED disabled by the use of the FEDACSDIS2 register (see [Section 5.8.31](#)).

Figure 5-15. Flash Error Detection and Correction Sector Disable Register (FEDACSDIS)

Table 5-21. Flash Error Detection and Correction Sector Disable Register (FEDACSDIS)
Field Descriptions

| Bit | Field | Value | Description |
|-------|-------------------|-------------|---|
| 31-29 | BankID1_Inverse | 0 other | The bank ID inverse bits are used with the bank ID bits to select the bank for which a sector is disabled. The only bank that supports sector disable is bank 7. If BankID1 = 7h and BankID1_inverse = 0, then if a valid sector is selected by SectorID1 and SectorID1_inverse that sector will have ECC checking disabled No sector is disabled by disable ID 1 |
| 28 | Reserved | 0 | Read returns 0. Writes have no effect. |
| 27-24 | SectorID1_inverse | | The sector ID inverse bits are used with the sector ID bits to determine which sector is disabled. If the sector ID bits are not pointing to a valid sector (0-3) or the sector ID inverse bits are not an inverse of the sector ID bits, then no sector is disabled by disable ID 1 |
| 23-21 | BankID1 | 7h other | The bank ID bits are used with the bank ID inverse bits to select the bank for which a sector is disabled. The only bank that supports sector disable is bank 7. If BankID1 = 7h and BankID1_inverse = 0, then if a valid sector is selected by SectorID1 and SectorID1_inverse that sector will have ECC checking disabled No sector is disabled by disable ID 1 |
| 20 | Reserved | 0 | Read returns 0. Writes have no effect. |
| 19-16 | SectorID1 | | The sector ID bits are used with the sector ID inverse bits to determine which sector is disabled. If the sector ID bits are not pointing to a valid sector (0-3) or the sector ID inverse bits are not an inverse of the sector ID bits, then no sector is disabled by disable ID 1 |
| 15-13 | BankID0_Inverse | 0 other | The bank ID inverse bits are used with the bank ID bits to select the bank for which a sector is disabled. The only bank that supports sector disable is bank 7. If BankID0 = 7h and BankID0_inverse = 0, then if a valid sector is selected by SectorID0 and SectorID0_inverse that sector will have ECC checking disabled No sector is disabled by disable ID 0 |
| 12 | Reserved | 0 | Read returns 0. Writes have no effect. |
| 11-8 | SectorID0_inverse | | The sector ID inverse bits are used with the sector ID bits to determine which sector is disabled. If the sector ID bits are not pointing to a valid sector (0-3) or the sector ID inverse bits are not an inverse of the sector ID bits, then no sector is disabled by disable ID 0 |
| 7-5 | BankID0 | 7h other | The bank ID bits are used with the bank ID inverse bits to select the bank for which a sector is disabled. The only bank that supports sector disable is bank 7. If BankID0 = 7h and BankID0_inverse = 0, then if a valid sector is selected by SectorID0 and SectorID0_inverse that sector will have ECC checking disabled No sector is disabled by disable ID 0 |
| 4 | Reserved | 0 | Read returns 0. Writes have no effect. |
| 3-0 | SectorID0 | 0-Fh | The sector ID bits are used with the sector ID inverse bits to determine which sector is disabled. If the sector ID bits are not pointing to a valid sector (0-3) or the sector ID inverse bits are not an inverse of the sector ID bits, then no sector is disabled by disable ID 0 |

5.8.10 Primary Address Tag Register (FPRIM_ADD_TAG)

This register is used to test the pipeline address tag registers (see [Section 5.7.2.5](#)).

Figure 5-16. Primary Address Tag Register (FPRIM_ADD_TAG) [offset = 28h]

LEGEND: R/W = Read/Write; R = Read only; WP=Write in Privilege Mode;; -n = value after reset;

Table 5-22. Primary Address Tag Register (FPRIM_ADD_TAG) Field Descriptions

| Bit | Field | Value | Description |
|------|--------------|-------|--|
| 31-4 | PRIM_ADD_TAG | | Primary Address Tag Register The primary address tag register selected via DIAG_BUF_SEL bits in FDIAGCTRL register is memory mapped here. (see Section 5.8.26) This register can only be written in privileged mode when diagnostic mode is enabled with DIAG_EN_KEY = 5h and DIAG_MODE = 5h. This register will not update with new flash data if DIAG_EN_KEY is not equal to 5h or DIAG_MODE is 0 or 7h. Valid reads can occur in any mode. The register will clear when an address tag error is found and when leaving DIAG_MODE 5. |
| 3-0 | | 0 | Always 0000 |

5.8.11 Duplicate Address Tag Register (FDUP_ADD_TAG)

This register is used to test the pipeline address tag registers (see [Section 5.7.2.5](#)).

Figure 5-17. Duplicate Address Tag Register (FDUP_ADD_TAG) [offset = 2Ch]

LEGEND: R/W = Read/Write; R = Read only; WP=Write in Privilege Mode;; -n = value after reset;

Table 5-23. Duplicate Address Tag Register (FDUP_ADD_TAG) Field Descriptions

| Bit | Field | Value | Description |
|------|-------------|-------|--|
| 31-4 | DUP_ADD_TAG | | Primary Address Tag Register The duplicate address tag register selected via DIAG_BUF_SEL bits in FDIAGCTRL register is memory mapped here. (see Section 5.8.26) This register can only be written in privileged mode when diagnostic mode is enabled with DIAG_EN_KEY = 5h and DIAG_MODE = 5h. This register will not update with new flash data if DIAG_EN_KEY is not equal to 5h or DIAG_MODE is 0 or 7h. Valid reads can occur in any mode. The register will clear when an address tag error is found and when leaving DIAG_MODE 5. |
| 3-0 | | 0 | Always 0000 |

5.8.12 Flash Bank Protection Register (FBPROT)

Figure 5-18. Flash Bank Protection Register (FBPROT) [offset = 30h]

LEGEND: R/W = Read/Write; R = Read only; WP=Write in Privilege Mode; -n = value after reset

Table 5-24. Flash Bank Protection Register (FBPROT) Field Descriptions

| Bit | Field | Value | Description |
|------|-----------|-------|---|
| 31-1 | Reserved | 0 | Read returns 0. Writes have no effect. |
| 0 | PROTL1DIS | | PROTL1DIS: Level 1 Protection Disabled Level 1 Protection Disable bit. Setting this bit disables protection from writing to the OTPPROTDIS bits as well as the Sector Enable registers FBSE for all banks. Clearing this bit enables protection and disables write access to the OTPPROTDIS register bits and FBSE register. |
| | | 0 | Level 1 protection is disabled. |
| | | 1 | Level 1 protection is enabled. |

5.8.13 Flash Bank Sector Enable Register (FBSE)

FBSE provides one enable bit per sector for up to 16 sectors per bank. Each bank in the Flash module has one FBSE register. The bank is selected via the BANK[2:0] bits of the FMAC register (see [Section 5.8.20](#)). As only one bank at a time can be selected by FMAC, only the register for the bank selected appears at this address.

Figure 5-19. Flash Bank Sector Enable Register (FBSE) [offset = 34h]

LEGEND: R/W = Read/Write; R = Read only; WP=Write in Privilege Mode; -n = value after reset

Table 5-25. Flash Bank Sector Enable Register (FBSE) Field Descriptions

| Bit | Field | Value | Description |
|-------|----------|-------|--|
| 31-16 | Reserved | 0 | Read returns 0. Writes have no effect. |
| 15-0 | BSE | | Bank Sector Enable Each bit corresponds to a flash sector in the bank specified by the FMAC register. Bit 0 corresponds to sector 0, bit 1 corresponds to sector 1, etc. These bits can be set only when PROTL1DIS = 1 and in privilege mode. |
| | | 0 | The corresponding numbered sector is disabled for program or erase access. |
| | | 1 | The corresponding numbered sector is enabled for program or erase access. |

5.8.14 Flash Bank Busy Register (FBBUSY)

Figure 5-20. Flash Bank Busy Register (FBBUSY) [offset = 38h]

LEGEND: R/W = Read/Write; R = Read only; WP=Write in Privilege Mode; -n = value after reset

Table 5-26. Flash Bank Busy Register (FBBUSY) Field Descriptions

| Bit | Field | Value | Description |
|------|-----------|---------------------------|---|
| 31-8 | Reserved | 0 | Read returns 0. Writes have no effect. |
| 7-0 | BUSY[7:0] | <div>0</div> <div>1</div> | <div>Bank Busy</div> <div>Each bit corresponds to a Flash bank.</div> <div>The corresponding bank is not busy</div> <div>The corresponding bank is busy with a state machine or bus 2 operation, or the bank is not implemented</div> |

5.8.15 Flash Bank Access Control Register (FBAC)

Figure 5-21. Flash Bank Access Control Register (FBAC) [offset = 3Ch]

| | | | |
|----------|----|------------|----|
| 31 | 24 | 23 | 16 |
| Reserved | | OTPPROTDIS | |
| R-0 | | R/WP-0 | |
| 15 | 8 | 7 | 0 |
| BAGP | | VREADST | |
| R/WP-0 | | R/WP-Fh | |

LEGEND: R/W = Read/Write; R = Read only; WP=Write in Privilege Mode; -n = value after reset

Table 5-27. Flash Bank Access Control Register (FBAC) Field Descriptions

| Bit | Field | Value | Description |
|-------|------------|--------|--|
| 31-24 | Reserved | 0 | Read returns 0. Writes have no effect. |
| 23-16 | OTPPROTDIS | 0 1 | OTP Sector Protection Disable. Each bit corresponds to a Flash bank. This bit can be set only when PROTL1DIS = 1 and in privilege mode. Programming of the OTP sector is disabled. Programming of the OTP sector is enabled. |
| 15-8 | BAGP | 0-FFh | Bank Active Grace Period. These bits contain the starting count value for the BAGP down counter. Any access to a given bank causes its BAGP counter to reload the BAGP value for that bank. After the last access to this Flash bank, the down counter delays from 0 to 255 prescaled HCLK clock cycles before putting the bank into one of the fallback power modes as determined by the FBFALLBACK register. This value must be greater than 1 when the fallback mode is not ACTIVE. Note: The prescaled clock used for the BAGP down counter is a clock divided by 16 from HCLK. |
| 7-0 | VREADST | 0-FFh | VREAD Setup. VREAD is generated by the Flash pump and used for Flash read operation. The bank power up sequencing starts VREADST HCLK cycles after VREAD power supply becomes stable. Note: There is not a programmable Bank Sleep counter and Standby counter register. The number of clock cycles to transition from sleep to standby and standby to active is hardcoded in the Flash wrapper design. |

5.8.16 Flash Bank Fallback Power Register (FBFALLBACK)

Figure 5-22. Flash Bank Fallback Power Register (FBFALLBACK) [offset = 40h]

| 14 | ILA | | <p>Illegal Address</p> <p>When set, indicates that an illegal address is detected. Five conditions can set the illegal address flag.</p> <ol style="list-style-type: none"> 1. Writing to a hole (un-implemented logical address space) within a flash bank. 2. Writing to an address location to an un-implemented flash space. 3. Input address for write is decoded to select a different bank from the bank ID register. 4. The address range does not match the type of FSM command. For example, the erase_sector command must match the address regions. 5. TI-OTP address selected but CMD_EN in FSM_ST_MACHINE is not set. |
| 13 | Reserved | 0 | Read returns 0. Writes have no effect. |
| 12 | PGV | | <p>Program Verify</p> <p>When set, indicates that a word is not successfully programmed after the maximum allowed number of program pulses are given for program operation.</p> |
| 11 | Reserved | 0 | Read returns 0. Writes have no effect. |
| 10 | EV | | <p>Erase Verify</p> <p>When set, indicates that a sector is not successfully erased after the maximum allowed number of erase pulses are given for erase operation. During Erase verify command, this flag is set immediately if a bit is found to be 0.</p> |
| 9 | Reserved | 0 | Read returns 0. Writes have no effect. |
| 8 | BUSY | | <p>Busy</p> <p>When set, this bit indicates that a program, erase, or suspend operation is being processed.</p> |
| 7 | ERS | | <p>Erase Active</p> <p>When set, this bit indicates that the flash module is actively performing an erase operation. This bit is set when erasing starts and is cleared when erasing is complete. It is also cleared when the erase is suspended and set when the erase resumes.</p> |
| 6 | PGM | | <p>Program Active</p> <p>When set, this bit indicates that the flash module is currently performing a program operation. This bit is set when programming starts and is cleared when programming is complete. It is also cleared when programming is suspended and set when programming is resumes.</p> |
| 5 | INVDAT | | <p>Invalid Data</p> <p>When set, this bit indicates that the user attempted to program a "1" where a "0" was already present. This bit is cleared by the Clear Status command.</p> |

Table 5-33. Flash Module Status Register (FMSTAT) Field Descriptions (continued)

| Bit | Field | Value | Description |
|-----|----------|-------|---|
| 4 | CSTAT | | <p>Command Status</p> <p>Once the FSM starts any failure will set this bit. When set, this bit informs the host that the program, erase, or validate sector command failed and the command was stopped. This bit is cleared by the Clear Status command. For some errors, this will be the only indication of an FSM error because the cause does not fall within the other error bit types.</p> |
| 3 | VOLTSTAT | | <p>Core Voltage Status</p> <p>When set, this bit indicates that the core voltage generator of the pump power supply dipped below the lower limit allowable during a program or erase operation. This bit is cleared by the Clear Status command.</p> |
| 2 | ESUSP | | <p>Erase Suspended</p> <p>When set, this bit indicates that the flash module has received and processed an erase suspend operation. This bit remains set until the erase resume command has been issued or until the Clear_More command is run.</p> |
| 1 | PSUSP | | <p>Program Suspended</p> <p>When set, this bit indicates that the flash module has received and processed a program suspend operation. This bit remains set until the program resume command has been issued or until the Clear_More command is run.</p> |
| 0 | SLOCK | | <p>Sector Lock Status</p> <p>When set, this bit indicates that the operation was halted because the target sector was locked for erasing and programming either by the sector protect bit or by OTP write protection disable bits. (Bits BSE in FBSE register or OTPPROTDIS in register FBAC). This bit is cleared by the Clear Status command.</p> <p>No SLOCK FSM error will occur if all sectors in a bank erase operation are set to 1. All the sectors will be checked but no SLOCK will be set if no operation occurs due to the SECT_ERASED bits being set to all ones. A SLOCK error will occur if attempting to do a sector erase with either BSE is cleared or SECT_ERASED is set</p> |

5.8.22 EEPROM Emulation Data MSW Register (FEMU_DMSW)

Table 5-37. EEPROM Emulation Address Register (FEMU_ADDR) Field Descriptions

| Bit | Field | Value | Description |
|-------|----------|-----------|---|
| 31-22 | Reserved | 0 | Reserved; writes have no affect. It is not necessary to mask these upper ten bits when writing the address of bank 7 locations (0xF002xxxx), however these bits are not used in calculating the ECC value and will read back as zero. |
| 21-3 | EMU_ADDR | 0-7 FFFFh | EEPROM Emulation Address This register contains the upper 19 bits of the 83-bit data used to calculate the ECC. When this register is written, the corresponding ECC word is updated in FEMU_ECC register. This register is also used in the diagnostic modes 1 and 2. In these modes, this register supplies the address bits 21:3 for checking the SECDDED. |
| 2-0 | Reserved | 0 | Reserved; writes have no affect. The lower three bits of the CPU address are not used in the ECC calculation to align the data on a 64-bit boundary. These bits will read back as zero. |

5.8.26 Diagnostic Control Register (FDIAGCTRL)

Set the DIAG_MODE and the DIAG_EN_KEY first before setting up the other registers to block the other registers from causing a false error. The final write should set the DIAG_TRIG register to activate the test. Running out of ram will prevent problems with the diagnostic test corrupting the flash access in some of the modes.

This register is present only when SIL3_config = 1, otherwise, this is an unimplemented location. Reads will return zeros; writes do nothing but no address error will be generated.

| R/WP-5h | | | | R/WP-2h | | | R/WP-0 | | R/WP-0 | | | | | | | | | |

LEGEND: R/W = Read/Write; R = Read only; WP=Write in Privilege Mode; -n = value after reset

Table 5-42. Parity Override Register (FPAR_OVR) Field Descriptions

| Bit | Field | Value | Description |
|-------|-------------|-------|---|
| 31-17 | Reserved | 0 | Reserved |
| 16 | BNK_INV_PAR | | Buffer Invert Parity When this value is one and PAR_OVR_KEY is '101' then the current system parity signal SYS_ODD_PARITY is inverted when doing bank parity calculations. This will generate parity errors and cause interrupt signals to be generated. When zero, the SYS_ODD_PARITY value is used. This bit is only implemented for parity configurations and is reserved for ECC devices. |
| 15-12 | BUS_PAR_DIS | | Disable Bus Parity When this value is "1010", the address bus parity error and buffer parity error are disabled and no checking is done and no events are generated. Any other value will enable the parity checking on the Address bus and read data bus. The read data parity is never disabled from this module. |
| 11-9 | PAR_OVR_KEY | | When this value is "101", the selected ADD_INV_PAR and DAT_INV_PAR fields will become active. Any other value will cause the module to use the global system parity bit in the system register DEVCR1. |
| 8 | ADD_INV_PAR | | Address Odd Parity This bit is active only when PAR_OVR_KEY = '101'. When ADD_INV_PAR is one, the incoming address bus will invert the system signal SYS_ODD_PARITY for parity calculations. This will cause parity errors and generate interrupt error signals. When zero it will use the SYS_ODD_PARITY value. This bit is set to the SYS_ODD_PAR signal value on reset. |
| 7-0 | DAT_INV_PAR | | Data Odd Parity This byte is active only when PAR_OVR_KEY = '101'. When a DATA_INV_PAR bit is one, the output read data will invert the system signal SYS_ODD_PARITY for parity calculations. This will cause parity errors and generate interrupt signals. When zero it will use the SYS_ODD_PARITY value. This byte can support up to a 64 bit data bus but when the device has a 32 bit bus, bits 7:4 are reserved. Bit 0 affects read bus bits 7:0, Bit 1 affects read bus bits 15:8 and so on. Each active bit of this field is set to the SYS_ODD_PAR signal value on reset. The DAT_INV_PAR is used in the parity for the pipeline buffer logic and for the read data bus to the CPU. When the ECC logic is in the CPU (CONF_TYPE = 5) and SIL3 is active, this field becomes the ECC corrupting value for SIL3 diagnostic mode 7. (Starting with version 1.0.0.0) In diagnostic mode 7 the FPAR_OVR should be set to 00005Axxh to allow writes to the DAT_INV_PAR field. This field should be written before entering diagnostic mode 7. |

5.8.31 Flash Error Detection and Correction Sector Disable Register (FEDACSDIS2)

This register is used to disable the SECDED function for one or two sectors from the EEPROM Emulation flash (bank 7). An additional two sectors can have SECDED disabled by the use of the FEDACSDIS register. see [Section 5.8.9](#).

Figure 5-37. Flash Error Detection and Correction Sector Disable Register (FEDACSDIS2)

Table 5-43. Flash Error Detection and Correction Sector Disable Register (FEDACSDIS2)
Field Descriptions

| Bit | Field | Value | Description |
|-------|-------------------|-------------|---|
| 31-29 | BankID3_Inverse | 0 other | The bank ID inverse bits are used with the bank ID bits to select the bank for which a sector is disabled. The only bank that supports sector disable is bank 7. If BankID3 = 7h and BankID3_inverse = 0, then if a valid sector is selected by SectorID3 and SectorID3_inverse that sector will have ECC checking disabled No sector is disabled by disable ID 3 |
| 28 | Reserved | 0 | Read returns 0. Writes have no effect. |
| 27-24 | SectorID3_inverse | | The sector ID inverse bits are used with the sector ID bits to determine which sector is disabled. If the sector ID bits are not pointing to a valid sector (0-3) or the sector ID inverse bits are not an inverse of the sector ID bits, then no sector is disabled by disable ID 3 |
| 23-21 | BankID3 | 7h other | The bank ID bits are used with the bank ID inverse bits to select the bank for which a sector is disabled. The only bank that supports sector disable is bank 7. If BankID3 = 7h and BankID3_inverse = 0, then if a valid sector is selected by SectorID3 and SectorID3_inverse that sector will have ECC checking disabled No sector is disabled by disable ID 3 |
| 20 | Reserved | 0 | Read returns 0. Writes have no effect. |
| 19-16 | SectorID3 | | The sector ID bits are used with the sector ID inverse bits to determine which sector is disabled. If the sector ID bits are not pointing to a valid sector (0-3) or the sector ID inverse bits are not an inverse of the sector ID bits, then no sector is disabled by disable ID 3 |
| 15-13 | BankID2_Inverse | 0 other | The bank ID inverse bits are used with the bank ID bits to select the bank for which a sector is disabled. The only bank that supports sector disable is bank 7. If BankID2 = 7h and BankID2_inverse = 0, then if a valid sector is selected by SectorID2 and SectorID2_inverse that sector will have ECC checking disabled No sector is disabled by disable ID 2 |
| 12 | Reserved | 0 | Read returns 0. Writes have no effect. |
| 11-8 | SectorID2_inverse | | The sector ID inverse bits are used with the sector ID bits to determine which sector is disabled. If the sector ID bits are not pointing to a valid sector (0-3) or the sector ID inverse bits are not an inverse of the sector ID bits, then no sector is disabled by disable ID 2 |
| 7-5 | BankID2 | 7h other | The bank ID bits are used with the bank ID inverse bits to select the bank for which a sector is disabled. The only bank that supports sector disable is bank 7. If BankID2 = 7h and BankID2_inverse = 0, then if a valid sector is selected by SectorID2 and SectorID2_inverse that sector will have ECC checking disabled No sector is disabled by disable ID 2 |
| 4 | Reserved | 0 | Read returns 0. Writes have no effect. |
| 3-0 | SectorID2 | 0-Fh | The sector ID bits are used with the sector ID inverse bits to determine which sector is disabled. If the sector ID bits are not pointing to a valid sector (0-3) or the sector ID inverse bits are not an inverse of the sector ID bits, then no sector is disabled by disable ID 2 |

5.8.32 FSM Register Write Enable (FSM_WR_ENA)

Figure 5-38. FSM Register Write Enable (FSM_WR_ENA) [offset = 288h]

LEGEND: R/W = Read/Write; R = Read only; WP=Write in Privilege Mode; -n = value after reset

Table 5-44. FSM Register Write Enable (FSM_WR_ENA) Field Descriptions

| Bit | Field | Value | Description |
|-------|----------|------------------|---|
| 31-16 | Reserved | 0 | Read returns 0. Writes have no effect. |
| 2-0 | WR_ENA | 5h | Flash State Machine Write Enable This register must contain "101" in order to write to any other register in the range FFF8 7200h to FFF8 72FFh. This is the first register to be written when setting up the FSM. |
| | | All other values | For all other values, the FSM registers cannot be written. |

5.8.33 FSM Sector Register (FSM_SECTOR)

This is a banked register. A separate register is implemented for each bank, but they all occupy the same address. The correct bank must be selected in the FMAC register before reading or writing this register. See [Section 5.8.20](#).

Figure 5-39. FSM Sector Register (FSM_SECTOR) [offset = 2A4h]

LEGEND: R/W = Read/Write; R = Read only; WP=Write in Privilege Mode; -n = value after reset

Table 5-45. FSM Sector Register (FSM_SECTOR) Field Descriptions

| Bit | Field | Value | Description |
|-------|-------------------|-------|--|
| 31-16 | SECT_ERASED[16:0] | | Sectors Erased There is one bit for each sector. Bit 16 corresponds to sector 0, bit 17 corresponds to sector 1, and so on. After bank erase, the bit corresponding to each sector which is erased will be changed from 0 to 1. |
| | | 0 | During bank erase, each sector will be erased. |
| | | 1 | Each sector will not be erased. |
| 15-0 | Reserved | 0 | These bits are used by the state machine during bank erase. Do not write to these bits. |

5.8.34 EEPROM Emulation Configuration Register (EEPROM_CONFIG)

Figure 5-40. EEPROM Emulation Configuration Register (EEPROM_CONFIG) [offset = 2B8h]

Table 5-46. EPROM Emulation Configuration Register (EEPROM_CONFIG) Field Descriptions

| Bit | Field | Value | Description |
|-------|-----------------|--------|--|
| 31-20 | Reserved | 0 | Read returns 0. Writes have no effect. |
| 19-16 | EWAIT | | EEPROM Wait state Counter This register will replace the RWAIT count in the EEPROM register. The same formulas that apply to RWAIT will apply to EWAIT in the EEPROM bank. |
| 15-9 | Reserved | 0 | Read returns 0. Writes have no effect. |
| 8 | AUTOSUSP_EN | 0 1 | Auto Suspend Enable Auto Suspend Disabled Auto Suspend Enabled The auto-suspend will begin when the CPU or Bus2 attempts to access a bank with an active and suspendable FSM operation. If this happens the FSM will automatically be issued a suspend command and exit from the FSM. It will then do the access. After the access, the FMC will wait for a time determined by the Autostart_grace field before issuing the FSM resume command. |
| 7-0 | AUTOSTART_GRACE | 1 0 | Auto-suspend Startup Grace Period The value in this register determines how many cycles the FMC will wait after the last CPU or Bus2 access before issuing the FSM resume command. The FMC will wait 16 HCLK periods for each count in the AUTOSTART_GRACE field. A value of 2 will wait for 32 periods after the last access. Each access will reset the counter to the AUTOSTART_GRACE value × 16. |

5.8.35 EEPROM Emulation Error Detection and Correction Control Register 1 (EE_CTRL1)

This register controls ECC parity detection.

Field Descriptions**

| Bit | Field | Value | Description |
|-------|-----------|---------|---|
| 31-16 | Reserved | 0 | Read returns 0. Writes have no effect. |
| 15-0 | EE_ERRCNT | 0-FFFFh | Single Error Correction Count This register contains the number of SEC (single error correction) occurrences. Writing any value to this register resets the count value to zero. The counter resets to zero when it increments to be equal to the single error correction threshold. This register only increments when profiling mode is enabled. This register is not affected by the EE_ZERO_EN or EE_ONE_EN error control bits in the EE_CTRL1 register. |

5.8.38 EEPROM Emulation Correctable Error Address Register (EE_COR_ERR_ADD)

During emulation mode, this address is frozen even when read. By setting the SUSP_IGNORE bit, (see [Table 5-14](#)) this register can be un-frozen in emulation mode.

This register is not changed with the reset signal and contains unknown data at powerup.

**Figure 5-44. EEPROM Emulation Correctable Error Address Register (EE_COR_ERR_ADD)
[offset = 314h]**

LEGEND: R = Read only; -n = value after reset; -u = unchanged value on internal reset, cleared on power up

**Table 5-50. EEPROM Emulation Correctable Error Address Register (EE_COR_ERR_ADD)
Field Descriptions**

| Bit | Field | Value | Description |
|------|-------------|--------------|--|
| 31-3 | COR_ERR_ADD | 0-1FFF FFFFh | Correctable Error Address COR_ERR_ADD records the CPU logical address of which a correctable error is detected by the ECC logic. This error address is frozen from begin updated until it is read by the CPU. Additional error are blocked until this register is read. |
| 2-0 | B_OFF | 0-7h | Byte offset Since ECC is checked on 64 bit data, when checking main memory or OTP, the address captured is aligned to a 64-bit boundary with address bits[2:0] equal to 0. When reading from the ECC bytes, these bits will indicate the failing address of the ECC location associated with the failure. When reading an ECC byte, the ECC is checked against the 64 data bits they protect. |

5.8.40 EEPROM Emulation Error Status Register (EE_STATUS)

During emulation mode, this address is frozen even when read. By setting the SUSP_IGNR bit, (see [Table 5-14](#)) this register can be un-frozen in emulation mode.

This register is not changed with the reset signal and contains unknown data at powerup.

All these error status bits can be deactivated by writing a one to the bit. Writing a zero has no effect.

Bits 0 to 3 show correctable errors while bits 4 to 12 show uncorrectable errors. When the uncorrectable errors are triggered, the current address is stored in the EE_UNC_ERR_ADD register.

These error bits are not set while the FMC is in the suspend mode but they can be cleared in suspend by writing 1s to the bits. By setting the SUSP_IGNR bit to '1' these error bits can be set in suspend mode (see [Table 5-14](#)).

| 6.6 Emulation / Debug Mode Behavior..... | 329 |
| 6.7 Control and Status Registers | 329 |

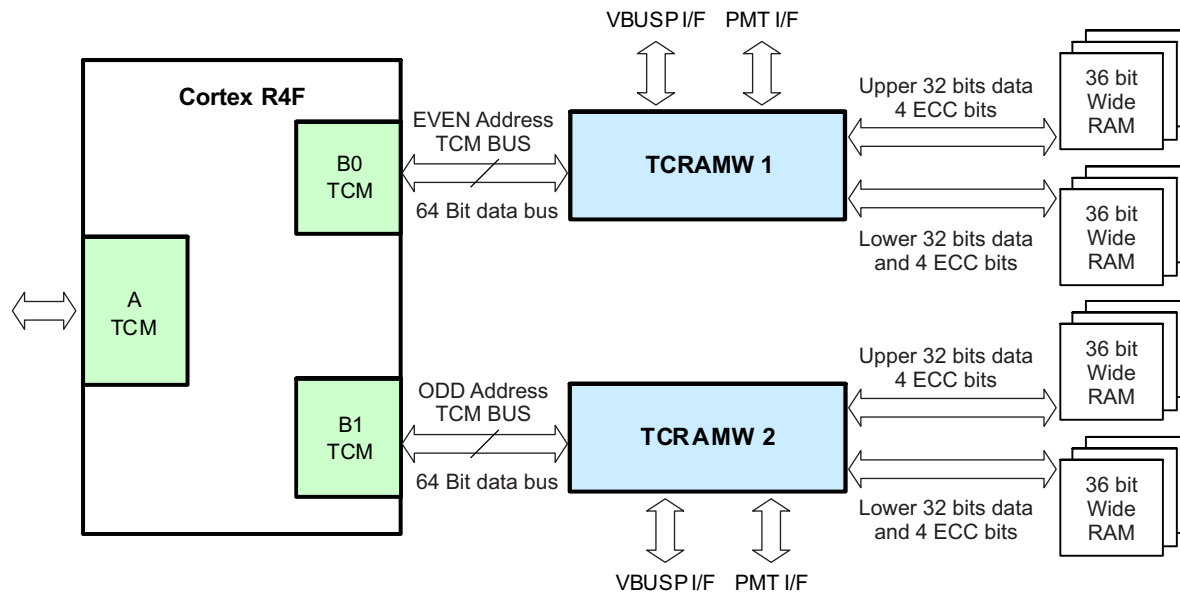

6.1 Overview

The Hercules family of microcontrollers are based on the ARM Cortex-R4F processor. This CPU has two tightly-coupled memory interfaces – ATCM and BTCM, which are used to interface to the program and data memories, respectively. The Hercules MCUs use the ATCM interface for the main flash memory and the BTCM interface for the CPU data RAM.

6.1.1 B0TCM and B1TCM Connection Diagram

The BTCM interface is further divided into two parts – B0TCM and B1TCM, which are both used to interface to actual RAM banks as shown in [Figure 6-1](#).

Figure 6-1. TCRAM Module Connections

6.1.2 Main Features

The main features of the tightly-coupled RAM interface module are:

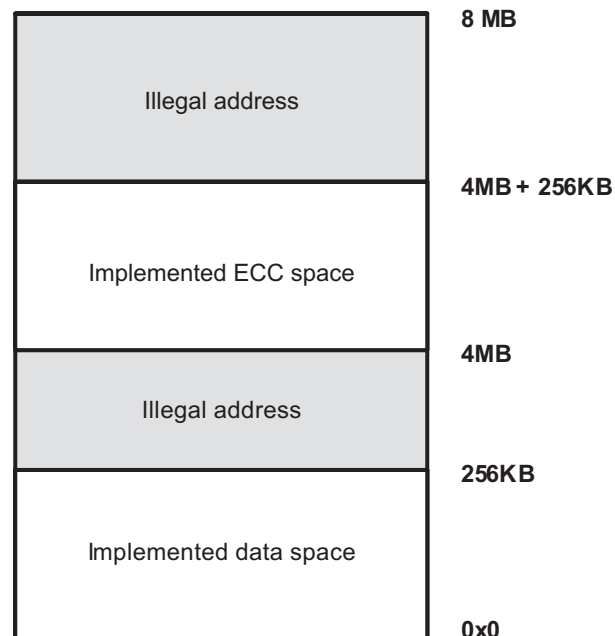

- Controls read/write accesses to the data RAM
- Decodes addresses within the memory region allocated for the RAM
- Supports read and write accesses in 64-bit, 32-bit, 16-bit or 8-bit access sizes
 - Does not support bit-wise operations
- Safety Features:
 - Support for Cortex-R4F CPU's Built-In Single-Error-Correction Double-Error-Detection (SECEDED) Logic
 - Uses the CPU's Event bus and maintains the SECEDED status in memory-mapped registers
 - Captures the number of occurrences of single-bit or multi-bit errors as well as the RAM address that has the fault
 - Generates signals for indicating single-bit and multi-bit errors to the Error Signaling Module (ESM)
 - Support for Cortex-R4F CPU's Parity Protection Logic for BTCM Address Bus and Control Signals
 - Uses the CPU's TCM Address Parity Scheme and indicates an address bus parity error to the ESM

- Redundant Address Decode Scheme
 - Checks the decoding of CPU address lines and generation of correct memory selects for the RAM banks
 - Also supports checking of the redundant address decode comparators themselves
- Supports auto-initialization of the CPU data RAM banks

6.2 RAM Memory Map

The ARM Cortex-R4F CPU allows up to 8MB to be accessed through the BTCM interface. The Hercules family of microcontrollers support up to 256KB RAM on the BTCM interface. Check the specific part's datasheet to identify the actual amount of TCRAM supported on the part. This RAM is protected by ECC allowing the CPU to correct any single-bit errors and detect double-bit errors within a 64-bit value. The error correction codes (ECC) are stored in the RAM memory space as well. The memory map for the TCRAM and the corresponding ECC space is shown in [Figure 6-2](#). Any access to an unimplemented TCRAM location results in an error response from the TCRAM module.

Figure 6-2. RAM Memory Map

Each RAM data word is 64 bits wide. These 64 bits are divided into two 32 bits per RAM bank as shown in [Figure 6-1](#). The 8 bits of ECC are also divided into 4 bits per RAM bank.

For every 64-bit read from the RAM, an 8-bit ECC is also read by the CPU on its ECC bus. Similarly, for every 64-bit write to the RAM, the CPU also writes an 8-bit ECC using the same ECC bus.

NOTE: Read-Modify-Write Requirement for Writes to RAM: The TCRAM interface module supports 64-bit, 32-bit, 16-bit or 8-bit writes to the RAM. However the ECC is calculated by the CPU for 64-bit values only. For any write access smaller than 64 bits, it is necessary to force the CPU to perform a 64-bit read-modify-write operation in order to ensure that the correct ECC is also written. This can be done by setting the bit 1: BTCMRMW of c15, the Secondary Auxiliary Control Register of the CPU. **This bit is already set by default.**

The ECC memory can also be directly accessed via memory-mapped offset addresses starting from 4MB, as shown in [Figure 6-2](#). A read from the ECC space results in the 8-bit ECC value appearing on each byte of the 64-bit CPU data. The ECC memory can only be written to as a 64-bit access. The write to the ECC space must also first be enabled via the RAM Control Register (RAMCTRL).

NOTE: No ECC Error Generated for Accesses to ECC Memory: A read from the ECC space send the ECC value on both the 64-bit TCM read data bus as well as the 8-bit ECC bus. This could result in the detection of a multi-bit error by the SECDED logic inside the CPU. The TCRAM interface module ignores the ECC error indicated by the CPU for the access to the ECC space.

6.3 Safety Features

The TCRAM interface module incorporates some features that are designed specifically with safety considerations. These are described in the following sections.

6.3.1 Support for Cortex-R4F CPU's Single-Error-Correction Double-Error-Detection (SECDED)

The TCRAM interface module monitors the CPU's event bus. The CPU's event bus signals single-bit or multi-bit errors for B0TCM as well as B1TCM separately. These signals are monitored by the TCRAM modules for each of these interfaces.

TCRAM Interface Module Features dedicated for SECDED Support:

- Dedicated single-bit error counter
 - This counter is stored in a memory-mapped register called [RAMOCCUR](#)
 - RAMOCCUR is used to count the single-bit errors corrected by the CPU's SECDED logic
 - The TCRAM interface module allows the application to generate an interrupt via the [RAMINTCTRL](#) register when the number of single-bit errors corrected by the CPU exceeds a programmable threshold, [RAMTHRESHOLD](#)
- RAM Error Status Register
 - The errors detected by the TCRAM interface module as well as those indicated by the CPU are flagged in the [RAMERRSTATUS](#) register
 - There are separate bits to indicate single-bit error, double-bit error, address decode failure, address compare logic failure, read-address parity failure, and write-address parity failure
- ECC Error Address Capture
 - Separate registers to hold the address on which a single-bit error is detected ([RAMSERRADDR](#)) or a double-bit error is detected ([RAMUERRADDR](#))
 - The RAMSERRADDR register is only updated when the RAMTHRESHOLD value is set to 1
 - Both the RAMSERRADDR and RAMUERRADDR capture the 64-bit-aligned address for the access to the TCRAM as an offset from the base address of the TCRAM (0x08000000 by default)

NOTE: Cortex-R4F CPU Event Bus Signaling Not Enabled By Default: Upon power-up and after a CPU reset, the event signaling mechanism inside the Cortex-R4F CPU is disabled. This feature must be enabled by setting the Export (X-bit) of the Performance Monitoring and Control Register (PMNC) in the CPU. The TCRAM interface module can only capture the single-bit or double-bit ECC error occurrences once the CPU's event signaling mechanism is enabled.

6.3.2 Support for Cortex-R4F CPU's Address and Control Bus Parity Checking

The Cortex-R4F CPU calculates a single parity-bit for the TCRAM address and control signals. The TCRAM interface module also computes this parity bit based on the CPU's address bus and control signals. The computed parity bit is compared against the parity bit received from the CPU. A mismatch is signaled as an Address Parity Failure to the Error Signaling Module (ESM) group2 channel 10 or 12. There is a separate address parity failure error channel for B0TCM and B1TCM.

The 64-bit TCRAM address which fails the parity check is captured in the [RAMPERRADDR](#) register as an offset from the base address of the TCRAM (0x08000000 by default). The TCRAM interface module also indicates the type of access, read or write, that failed the parity check. This is indicated by the [RADDR_PAR_FAIL](#) or the [WADDR_PAR_FAIL](#) status flags in the [RAMERRSTATUS](#) register.

The [RAMERRSTATUS](#) and [RAMPERRADDR](#) registers must be cleared by the application in order for the TCRAM interface module to continue capturing subsequent errors and error addresses.

The parity scheme used for the described parity checking mechanism is defined by the global system parity selection. This can be configured using the [DEVPARSEL](#) field of the [DEVCR1](#) control register in the system module. This device-wide parity scheme can be overridden inside the TCRAM interface module by configuring the Address Parity Override field in the [RAMCTRL](#) register.

NOTE: No Change Of Parity Scheme On-The-Fly: The TCRAM interface module does not support on-the-fly change to the parity scheme being used for checking the CPU address bus and control bus. The application must ensure that the parity polarity (odd or even) is not changed while there is an ongoing access to the TCRAM.

6.3.3 Redundant Address Decode

The TCRAM interface module generates the memory selects for each of the TCRAM banks as well as the ECC memory based on the CPU address. The logic to generate these memory selects is duplicated and the outputs compared to detect any address decode errors. A mismatch is indicated as an Address Error to the Error Signaling Module (ESM), one signal for B0TCM and one for B1TCM. The TCRAM or ECC address that caused the fault is captured in the [RAMUERRADDR](#) register. This 64-bit-aligned address is stored as an offset from the base of the TCRAM or ECC memory.

As described earlier, each individual physical RAM bank is 36 bits wide. Each RAM bank contributes 32 bits of data and 4 bits of ECC when the bus master performs a 64-bit read from the TCRAM. Each TCRAM bank receives a memory select and the address from the TCRAM interface module. Any difference between the address and the memory selects results in wrong data and ECC pair being sent to the CPU. The CPU's SECDED block will detect this data error.

The TCRAM interface module also supports a mechanism to test the operation of the redundant address decode logic and the compare logic. This testing is supported by providing a test stimulus, and can be triggered by the application by configuring the [RAMTEST](#) register. The address of any error identified during testing of the redundant address decode and compare logic is not captured in the [RAMUERRADDR](#) register.

NOTE: Address decode checking when in compare logic test mode: When the address decode and compare logic test mode is enabled, the redundant address decode and compare logic is not available for checking the proper generation of the memory selects for the TCRAM and ECC memory.

6.4 TCRAM Auto-Initialization

The RAM memory can be initialized by using the dedicated auto-initialization hardware. The TCRAM Module initializes the entire memory when the auto-init is enabled for the RAM. All RAM data memory is initialized to zeros and the ECC memory is initialized to the correct ECC value for zeros, that is, 0Ch.

6.5 Trace Module Support

No data is traced for an access to ECC memory.

6.6 Emulation / Debug Mode Behavior

The following describes the behavior of the TCRAM Module when in debug mode:

- The [RAMOCCUR](#) register continues to count the single-bit error corrections performed by the Cortex-R4F CPU's SECDED logic.
- No single-bit error interrupt is generated nor is any single-bit error address captured even when the RAMOCCUR counter reaches the programmed single-bit error correction threshold.
- No uncorrectable error interrupt is generated nor is any double-bit error address captured.
- No address parity error interrupt is generated nor is any parity error address captured.
- The [RAMUERRADDR](#) register is not cleared by a read in debug mode.
 - That is, if a double-bit error address is captured and is not read by the CPU before entering debug mode, then it remains frozen during debug mode even if it is read.
- The [RAMPERADDR](#) register is not cleared by a read in debug mode.

6.7 Control and Status Registers

The TCRAM Module registers are accessed through the system module registers' space in the Cortex-R4F CPU's memory map. All registers are 32-bit wide and are located on a 32-bit boundary. Reads and writes to registers are supported in 8-, 16-, and 32-bit accesses. The base address for the control registers is FFFF F800h for even RAM ECC and FFFF F900h for odd RAM ECC.

Table 6-1. TCRAM Module Control and Status Registers

| Offset | Acronym | Register Description | Section |
|--------|----------------|---|--------------------------------|
| 00h | RAMCTRL | TCRAM Module Control Register | Section 6.7.1 |
| 04h | RAMTHRESHOLD | TCRAM Module Single-Bit Error Correction Threshold Register | Section 6.7.2 |
| 08h | RAMOCCUR | TCRAM Module Single-Bit Error Occurrences Control Register | Section 6.7.3 |
| 0Ch | RAMINTCTRL | TCRAM Module Interrupt Control Register | Section 6.7.4 |
| 10h | RAMERRSTATUS | TCRAM Module Error Status Register | Section 6.7.5 |
| 14h | RAMSERRADDR | TCRAM Module Single-Bit Error Address Register | Section 6.7.6 |
| 1Ch | RAMUERRADDR | TCRAM Module Uncorrectable Error Address Register | Section 6.7.7 |
| 30h | RAMTEST | TCRAM Module Test Mode Control Register | Section 6.7.8 |
| 38h | RAMADDRDECVECT | TCRAM Module Test Mode Vector Register | Section 6.7.9 |
| 3Ch | RAMPERADDR | TCRAM Module Parity Error Address Register | Section 6.7.10 |

6.7.1 TCRAM Module Control Register (RAMCTRL)

The RAMCTRL register, shown in Figure 6-3 and described in Table 6-2, controls the safety features supported by the TCRAM Module.

Figure 6-3. TCRAM Module Control Register (RAMCTRL) [offset = 00h]

| | | | |
|----------|----|----------------------|-----------|
| 31 | 28 | 27 | 24 |
| Reserved | | ADDR_PARITY_OVERRIDE | |
| R-0 | | R/WP-0 | |
| 23 | 20 | 19 | 16 |
| Reserved | | ADDR_PARITY_DISABLE | |
| R-0 | | R/WP-5h | |
| 15 | 9 | | 8 |
| Reserved | | | ECC_WR_EN |
| R-0 | | | R/WP-0 |
| 7 | 4 | 3 | 0 |
| Reserved | | ECC_DETECT_EN | |
| R-0 | | R/WP-Ah | |

LEGEND: R/W = Read/Write; R = Read only; WP = Write in privileged mode only; -n = value after reset

Table 6-2. TCRAM Module Control Register (RAMCTRL) Field Descriptions

| Bit | Field | Value | Description |
|-------|----------------------|------------------|---|
| 31-28 | Reserved | 0 | Read returns 0. Writes have no effect. |
| 27-24 | ADDR_PARITY_OVERRIDE | Dh All Others | Address Parity Override. This field, when set to Dh, will invert the parity scheme selected by the device global parity selection. The address parity checker would then work on the inverted parity scheme. By default, the parity scheme is the same as the global device parity scheme. Parity scheme is opposite to the device global parity scheme. Parity scheme is the same as the device global parity scheme. |
| 23-20 | Reserved | 0 | Read returns 0. Writes have no effect. |
| 19-16 | ADDR_PARITY_DISABLE | Ah All Others | Address Parity Detect Disable. This field, when set to Ah, disables the parity checking for the address bus. The parity checking is enabled when this field is set to any other value. Note: The application must ensure that the WADDR_PAR_FAIL and RADDR_PAR_FAIL bits in RAMERRSTATUS register are cleared before enabling address parity checking. Address parity checking is disabled Address parity checking is enabled |
| 15-9 | Reserved | 0 | Read returns 0. Writes have no effect. |
| 8 | ECC_WR_EN | 0 1 | ECC Memory Write Enable. This bit is provided to prevent accidental writes to the ECC memory. A write access to the ECC memory is allowed only when the ECC_WR_EN bit is set to 1. If this bit is cleared, then any writes to ECC memory are ignored. Note: Reads are allowed from the ECC memory regardless of the state of the ECC_WR_EN bit. ECC memory writes are disabled. ECC memory writes are enabled. |
| 7-4 | Reserved | 0 | Read returns 0. Writes have no effect. |
| 3-0 | ECC_DETECT_EN | 5h All Others | ECC Detect Enable. This is a 4-bit key to enable the ECC detection feature in the TCRAM Module. If this field is set to any value other than 5h, then the TCRAM Module starts monitoring the TCM event bus and generates the corresponding error status flags. The error status updates are done only when the ECC_DETECT_EN field is not 5h. The ECC detection is enabled by default, as the ECC_DETECT_EN field default value is Ah. ECC detection is disabled. ECC detection is enabled. |

6.7.2 TCRAM Module Single-Bit Error Correction Threshold Register (RAMTHRESHOLD)

The RAMTHRESHOLD register, shown in [Figure 6-4](#) and described in [Table 6-3](#), allows the application to configure the number of single-bit error corrections by the SECDED logic inside the Cortex-R4F CPU before generating a single-bit error interrupt.

Figure 6-4. TCRAM Module Single-Bit Error Correction Threshold Register (RAMTHRESHOLD)
[offset = 04h]

| | |

| 15 | 0 |
| THRESHOLD | |
| R/WP-0 | |

LEGEND: R/W = Read/Write; R = Read only; WP = Write in privileged mode only; -n = value after reset

Table 6-3. TCRAM Module Single-Bit Error Correction Threshold Register (RAMTHRESHOLD)
Field Descriptions

| Bit | Field | Value | Description |
|-------|-----------|-------|--|
| 31-16 | Reserved | 0 | Read returns 0. Writes have no effect. |
| 15-0 | THRESHOLD | | Single-bit Error Threshold Count. This field contains the threshold value for the Single-bit Error Correction (SEC) occurrences before the single-bit error interrupt is generated. If this threshold is set to 1 then all single-bit error addresses are captured. To enable the error occurrence detection, the threshold must be set to a non-zero value. |

6.7.3 TCRAM Module Single-Bit Error Occurrences Counter Register (RAMOCCUR)

The RAMOCCUR register, shown in [Figure 6-5](#) and described in [Table 6-4](#), indicates the number of single-bit error corrections performed by the SEC logic inside the Cortex-R4F CPU.

Figure 6-5. TCRAM Module Single-Bit Error Occurrences Counter Register (RAMOCCUR)
[offset = 08h]

| | | |
|--------|--------------------------|----|
| 31 | Reserved | 16 |
| R-0 | | |
| 15 | SINGLE_ERROR_OCCURRENCES | 0 |
| R/WP-0 | | |

LEGEND: R/W = Read/Write; R = Read only; WP = Write in privileged mode only; -n = value after reset

Table 6-4. TCRAM Module Single-Bit Error Occurrences Counter Register (RAMOCCUR)
Field Descriptions

| Bit | Field | Value | Description |
|-------|--------------------------|-------|---|
| 31-16 | Reserved | 0 | Read returns 0. Writes have no effect. |
| 15-0 | SINGLE_ERROR_OCCURRENCES | | <p>Single-bit Error Correction Occurrences. This 16-bit counter contains the number of single-bit error occurrences. RAMOCCUR is reset to zero when it becomes equal to the THRESHOLD value set in the RAMTHRESHOLD register. The application must clear the RAMOCCUR register by writing 0x0 before setting the THRESHOLD value. If the RAMOCCUR value is already higher than the programmed THRESHOLD value then the counter increments and wraps around (overflow) to zero.</p> <p>Note: If the application tries to clear the RAMOCCUR register at the same time as the TCRAM Module tried to update it, then the TCRAM Module takes priority.</p> <p>Note: When the RAMTHRESHOLD register is set to 1, then the RAMOCCUR register must be cleared whenever a single-bit error correction occurs in order to count subsequent single-bit error corrections.</p> |

6.7.4 TCRAM Module Interrupt Control Register (RAMINTCTRL)

The RAMINTCTRL register, shown in [Figure 6-6](#) and described in [Table 6-5](#), enables the generation of an interrupt to the CPU whenever the number of single-bit error corrections (RAMOCCUR) reaches the programmed threshold (RAMTHRESHOLD).

Figure 6-6. TCRAM Module Interrupt Control Register (RAMINTCTRL) [offset = 0Ch]

| | | |

Table 6-5. TCRAM Module Interrupt Control Register (RAMINTCTRL) Field Descriptions

| Bit | Field | Value | Description |
|------|----------|-------|--|
| 31-1 | Reserved | 0 | Read returns 0. Writes have no effect. |
| 0 | SERR_EN | | <p>Single-bit Error Correction Interrupt Enable. This bit, when set to 1, enables the generation of the single-bit error interrupt when the RAMOCCUR count reaches the programmed RAMTHRESHOLD. If the interrupt is not enabled, the single-bit error counter continues to count by resetting back to zero without generating any error interrupt. The SERR status flag in the RAMERRSTATUS register gets set regardless of whether the SERR interrupt is enabled or not.</p> <p>0 Single-bit error generation is disabled.</p> <p>1 Single-bit error generation is enabled.</p> |

6.7.5 TCRAM Module Error Status Register (RAMERRSTATUS)

The RAMERRSTATUS register, shown in Figure 6-7 and described in Table 6-6, indicates the status of the various error conditions monitored by the TCRAM Module.

Figure 6-7. TCRAM Module Error Status Register (RAMERRSTATUS) [offset = 10h]

| | | | | | | | | | | | | | | | | |
|----------|----------|----------|------------------------|----------|----------------|----------|----------|--|--|------------------|----|------------------|---|--|--|----|
| 31 | Reserved | | | | | | | | | | | | | | | 16 |
| R-0 | | | | | | | | | | | | | | | | |
| 15 | Reserved | | | | | | | | | | 10 | 9 | 8 | | | |

| R-0 | | R/W1CP-0 | R/W1CP-0 | R-0 | R/W1CP-0 | R-0 | R/W1CP-0 | | | | | | | | | |

LEGEND: R/W = Read/Write; R = Read only; W1CP = Write 1 to clear in privilege mode only; -n = value after reset

Table 6-6. TCRAM Module Error Status Register (RAMERRSTATUS) Field Descriptions

| Bit | Field | Value | Description |
|-------|----------------------|-------|--|
| 31-10 | Reserved | 0 | Read returns 0. Writes have no effect. |
| 9 | WADDR_PAR_FAIL | | This bit indicates a Write Address Parity Failure. This bit must be cleared by writing 1 to it in order to enable the capture of parity error address for subsequent failures. This bit must be in a cleared state for generation of any new parity error interrupt. |
| 8 | RADDR_PAR_FAIL | | This bit indicates a Read Address Parity Failure. This bit must be cleared by writing 1 to it in order to enable the capture of parity error address for subsequent failures. This bit must be in a cleared state for generation of any new parity error interrupt. |
| 7-6 | Reserved | 0 | Read returns 0. Writes have no effect. |
| 5 | DERR | | This bit indicates a multi-bit error detected by the Cortex-R4F SECCED logic. |
| 4 | ADDR_COMP_LOGIC_FAIL | | Address decode logic element failed. This bit indicates that the redundant address decode logic test scheme has detected that a compare element has malfunctioned during the testing of the logic. This bit has to be cleared by writing 1 to it in order to enable the capture of uncorrectable error address for subsequent failures. This bit has to be in a cleared state for generation of a new uncorrectable error interrupt. This bit only gets set in the test mode, and has no relevance in functional mode. |
| 3 | Reserved | 0 | Read returns 0. Writes have no effect. |
| 2 | ADDR_DEC_FAIL | | Address decode failed. This bit indicates that an address error interrupt was generated by the redundant address decode and compare logic due to a functional failure. This bit must be cleared by writing 1 to it in order to enable the capture of uncorrectable error address for subsequent failures. This bit has to be in a cleared state for generation of a new address error interrupt. |
| 1 | Reserved | 0 | Read returns 0. Writes have no effect. |
| 0 | SERR | | Single Error Status. This bit indicates that the single-bit error threshold has been reached. This bit is set even if the single-bit error threshold interrupt is disabled. This bit must be cleared by writing 1 to it in order to clear the interrupt request and to enable subsequent single-bit error interrupt generation. |

NOTE: For equality test:

- If the comparator matches (no true silicon fail), there is no status bit set for ADDR_COMP_LOGIC_FAIL or ADDR_DEC_FAIL.
- If there is true silicon malfunction, ADDR_COMP_LOGIC_FAIL and ADDR_DEC_FAIL will be set, no UERRADDRESS is captured.

For inequality test, the compare vector will not match since non-inverted and inverted values of the same test vector are fed to the comparator:

- If there is no silicon malfunction on any of the comparator bits, then only ADDR_DEC_FAIL will be set. This is chosen so that we can ensure the functional ADDR_DEC_FAIL status bit data path can be tested.
- If there is a silicon malfunction on any of the comparator bits, then, ADDR_COMP_LOGIC_FAIL and ADDR_DEC_FAIL will be set, no UERRADDRESS is captured.

6.7.6 TCRAM Module Single-Bit Error Address Register (RAMSERRADDR)

The RAMSERRADDR register, shown in [Figure 6-8](#) and described in [Table 6-7](#), captures the address for which the Cortex-R4F CPU detected a single-bit error.

NOTE: The SERR bit in the RAMERRSTATUS register must be cleared, by writing 1 to the bit, in order to enable the RAMSERRADDR register to capture a subsequent new error address.

Figure 6-8. TCRAM Module Single-Bit Error Address Register (RAMSERRADDR)
[offset = 14h]

LEGEND: R = Read only; -n = value after reset

Table 6-7. TCRAM Module Single-Bit Error Address Register (RAMSERRADDR)
Field Descriptions

| Bit | Field | Value | Description |
|-------|----------------------|-------|---|
| 31-18 | Reserved | 0 | Read returns 0. Writes have no effect. |
| 17-3 | SINGLE_ERROR_ADDRESS | | <p>This register captures bits 17-3 of the address for which the Cortex-R4F CPU detects a single-bit error when the RAMTHRESHOLD register is set to 1. The lower 3 bits are always tied to zero so that the address captured is a double-word (64-bit) address. This is a 64-bit-aligned address is stored as an offset from the base of the TCRAM or ECC memory.</p> <p>This register can only be reset by asserting power-on reset, and holds the last error address even after a system reset.</p> |
| 2-0 | Reserved | 0 | Read returns 0. Writes have no effect. |

6.7.7 TCRAM Module Uncorrectable Error Address Register (RAMUERRADDR)

The RAMUERRADDR register, shown in [Figure 6-9](#) and described in [Table 6-8](#), captures the address for which the Cortex-R4F CPU detected a multi-bit error.

Figure 6-9. TCRAM Module Uncorrectable Error Address Register (RAMUERRADDR)
[offset = 1Ch]

| | | | | | |
|-----------------------------|--|----|----|-----------------------------|----|

| 15 | | | | 3 | 2 |
| UNCORRECTABLE_ERROR_ADDRESS | | | | Reserved | |
| R-0 | | | | R-0 | |

LEGEND: R = Read only; -n = value after reset

Table 6-8. TCRAM Module Uncorrectable Error Address Register (RAMUERRADDR)
Field Descriptions

| Bit | Field | Value | Description |
|-------|-----------------------------|-------|--|
| 31-23 | Reserved | 0 | Read returns 0. Writes have no effect. |
| 22-3 | UNCORRECTABLE_ERROR_ADDRESS | | <p>This register captures the address for which there was an uncorrectable error. The uncorrectable error is indicated by the Cortex-R4F CPU's SECEDED logic.</p> <p>For the SECEDED multi-bit or double-bit uncorrectable error this register stores bits 17-3 of the TCM access address. The lower 3 bits 2-0 are always read as zeros to indicate that the latched address is a double-word address. The address bits 31-18 are read as zeros. This is a 64-bit-aligned address is stored as an offset from the base of the TCRAM or ECC memory.</p> <p>For a redundant address decode and compare logic error this register stores the complete TCM access address rounded to a double-word boundary (bits 22-3). This error is also indicated by the ADDR_DEC_FAIL flag in the RAMERRSTATUS register. No error address is stored as a result of a redundant address logic test.</p> <p>The register has to be read-cleared to enable further error address captures. Reading the register does not clear its contents but enables the register to be updated with an uncorrectable error address.</p> <p>This register can only be reset by asserting power-on reset, and holds the last error address even after a system reset.</p> |
| 2-0 | Reserved | 0 | Read returns 0. Writes have no effect. |

6.7.8 TCRAM Module Test Mode Control Register (RAMTEST)

The RAMTEST register, shown in Figure 6-10 and described in Table 6-9, controls the test mode of the TCRAM Module.

Figure 6-10. TCRAM Module Test Mode Control Register (RAMTEST) [offset = 30h]

| | | | | | | | | | | | | | | | | | | | |
|----------|--|--|--|--|--|--|--|---|---------|---|-----------|---|----------|---|-------------|--|----|---|--|
| 31 | | | | | | | | | | | | | | | | | 16 | | |
| Reserved | | | | | | | | | | | | | | | | | | | |
| R-0 | | | | | | | | | | | | | | | | | | | |
| 15 | | | | | | | | 9 | 8 | 7 | 6 | 5 | 4 | 3 | | | | 0 | |
| Reserved | | | | | | | | | TRIGGER | | TEST_MODE | | Reserved | | TEST_ENABLE | | | | |
| R-0 | | | | | | | | | R/WP-0 | | R/WP-0 | | R-0 | | R/WP-5h | | | | |

LEGEND: R/W = Read/Write; R = Read only; WP = Write in privileged mode only; -n = value after reset

Table 6-9. TCRAM Module Test Mode Control Register (RAMTEST) Field Descriptions

| Bit | Field | Value | Description |
|------|-------------|------------------|--|
| 31-9 | Reserved | 0 | Read returns 0. Writes have no effect. |
| 8 | TRIGGER | | Test Trigger. This is an auto reset test trigger used to test the redundant address decode and compare logic. A redundant address decode test is executed when test mode is enabled and the test trigger is applied by writing a 1 to this bit. The trigger is valid only if test is enabled and the correct mode is configured in the TEST_MODE field, and the ADDR_DEC_FAIL, ADDR_COMP_LOGIC_FAIL, and DERR flags are cleared in the RAMERRSTATUS register and the RAMUERRADDR register is read-cleared. |
| 7-6 | TEST_MODE | 1h 2h | Test Mode. This field selects either equality or inequality testing schemes. If TEST_MODE is set to 1h, inequality check is done. The test stimulus stored in ADDRTEST_VECT register is inverted and fed into one channel and the non-inverted vector is fed into the other channel. If the XOR of these inputs is zero then the UERR interrupt is generated and ADDR_COMP_LOGIC_FAIL flag is set in RAMERRSTATUS register. If TEST_MODE is set to 2h, equality check is done. The test stimulus stored in ADDRTEST_VECT register is fed directly to both the channels of the comparator. If the XOR of these two inputs is not zero then UERR interrupt is generated and ADDR_COMP_LOGIC_FAIL flag is set in RAMERRSTATUS register. |
| 5-4 | Reserved | 0 | Read returns 0. Writes have no effect. |
| 3-0 | TEST_ENABLE | Ah All Others | Test Enable. This is a 4-bit key to enable the redundant address decode and compare logic test scheme. If the test scheme is enabled then the compare logic uses the test vector inputs from the ADDRTEST_VECT register. The functional path comparison is disabled when test mode is enabled. Test mode is enabled. Test mode is disabled. |

NOTE: For equality test:

- If the comparator matches (no true silicon fail), there is no status bit set for ADDR_COMP_LOGIC_FAIL or ADDR_DEC_FAIL.
- If there is true silicon malfunction, ADDR_COMP_LOGIC_FAIL and ADDR_DEC_FAIL will be set, no UERRADDRESS is captured.

For inequality test, the compare vector will not match since non-inverted and inverted values of the same test vector are fed to the comparator:

- If there is no silicon malfunction on any of the comparator bits, then only ADDR_DEC_FAIL will be set. This is chosen so that we can ensure the functional ADDR_DEC_FAIL status bit data path can be tested.
- If there is a silicon malfunction on any of the comparator bits, then, ADDR_COMP_LOGIC_FAIL and ADDR_DEC_FAIL will be set, no UERRADDRESS is captured.

6.7.9 TCRAM Module Test Mode Vector Register (RAMADDRDECVECT)

The RAMADDRDECVECT register, shown in Figure 6-11 and described in Table 6-10, is used for testing the redundant address decode and compare logic of the TCRAM Module.

Figure 6-11. TCRAM Module Test Mode Vector Register (RAMADDRDECVECT) [offset = 38h]

| | | | | |
|----------|-----------------|------------|----------|----|
| 31 | 27 | 26 | 25 | 16 |
| Reserved | | ECC_SELECT | Reserved | |

| 15 | RAM_CHIP_SELECT | | | 0 |
| R/WP-0 | | | | |

LEGEND: R/W = Read/Write; R = Read only; WP = Write in privileged mode only; -n = value after reset

Table 6-10. TCRAM Module Test Mode Vector Register (RAMADDRDECVECT) Field Descriptions

| Bit | Field | Value | Description |
|-------|-----------------|-------|--|
| 31-27 | Reserved | 0 | Read returns 0. Writes have no effect. |
| 26 | ECC_SELECT | | ECC Select. This bit is used to store the ECC select value for the redundant address decode and compare logic. The stored value is passed as test stimulus for the built-in test scheme. |
| 25-16 | Reserved | 0 | Read returns 0. Writes have no effect. |
| 15-0 | RAM_CHIP_SELECT | | RAM Chip Select. This field is used to store the RAM chip select value for the redundant address decode and compare logic. The stored value is passed as test stimulus for the built-in test scheme. |

6.7.10 TCRAM Module Parity Error Address Register (RAMPERRADDR)

The RAMPERRADDR register, shown in Figure 6-12 and described in Table 6-11, stores the address for which an address-parity error was detected.

Figure 6-12. TCRAM Module Parity Error Address Register (RAMPERRADDR) [offset = 3Ch]

| | | | |
|------------------------------|----|------------------------------|----------|
| 31 | 23 | 22 | 16 |

| 15 | 3 | 2 | 0 |
| ADDRESS_PARITY_ERROR_ADDRESS | | | Reserved |
| R-U | | | R-0 |

LEGEND: R = Read only; U = Undefined; -n = value after reset

Table 6-11. TCRAM Module Parity Error Address Register (RAMPERRADDR) Field Descriptions

| Bit | Field | Value | Description |
|-------|------------------------------|-------|---|
| 31-23 | Reserved | 0 | Read returns 0. Writes have no effect. |
| 22-3 | ADDRESS_PARITY_ERROR_ADDRESS | | Parity Error Address. This register stores the double-word boundary (bits 22-3) of the TCM access address for which there was an address parity error. This register must be read-cleared to enable further error address captures. Reading the register does not clear the register contents but enables the register to be updated with a new parity error address. This is a 64-bit-aligned address is stored as an offset from the base of the TCRAM or ECC memory. |
| 2-0 | Reserved | 0 | Read returns 0. Writes have no effect. |

Programmable Built-In Self-Test (PBIST) Module

This chapter describes the programmable built-in self-test (PBIST) controller module used for testing the on-chip memories on the Hercules microcontrollers.

| Topic | Page |
|--|-------------|
| 7.1 Overview | 339 |
| 7.2 RAM Grouping and Algorithm | 340 |
| 7.3 PBIST Flow | 341 |
| 7.4 Memory Test Algorithms on the On-chip ROM | 343 |
| 7.5 PBIST Control Registers | 345 |
| 7.6 PBIST Configuration Example | 358 |

7.1 Overview

The PBIST (Programmable Built-In Self-Test) controller architecture provides a run-time-programmable memory BIST engine for varying levels of coverage across many embedded memory instances.

7.1.1 Features of PBIST

- Information regarding on-chip memories, memory groupings, memory background patterns and test algorithms stored in dedicated on-chip PBIST ROM
- Host processor interface to configure and start BIST of memories
- Supports testing of PBIST ROM itself as well
- Supports testing of each memory at its maximum access speed in application
- Implements intelligent clock gating to conserve power

NOTE: Refer to the device datasheet for the maximum PBIST ROM clock frequency supported.

7.1.2 PBIST vs. Application Software-Based Testing

The PBIST architecture consists of a small coprocessor with a dedicated instruction set targeted specifically toward testing memories. This coprocessor executes test routines stored in the PBIST ROM and runs them on multiple on-chip memory instances. The on-chip memory configuration information is also stored in the PBIST ROM. The testing is done in parallel for each of the CPU data RAMs, while it is done sequentially for the rest of the memories.

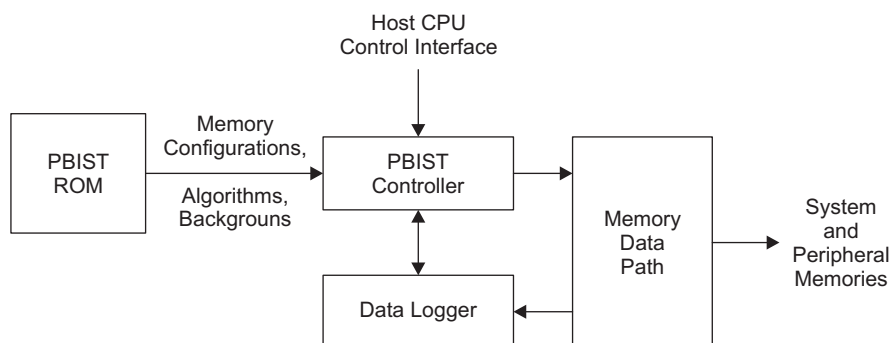

The PBIST Controller architecture offers significant advantages over tests running on the main Cortex-R4F processor (application software-based testing):

- Embedded CPUs have a long access path to memories outside the tightly-couple memory sub-system, while the PBIST controller has a dedicated path to the memories specifically for the self-test
- Embedded CPUs are designed for their targeted use and are often not easily programmed for memory test algorithms.
- The memory test algorithm code on embedded CPUs is typically significantly larger than that needed for PBIST.
- The embedded CPU is significantly larger than the PBIST controller.

7.1.3 PBIST Block Diagram

Figure 7-1 illustrates the basic PBIST blocks and its wrapper logic for the device.

Figure 7-1. PBIST Block Diagram

7.1.3.1 On-chip ROM

The on-chip ROM contains the information regarding the algorithms and memories to be tested.

7.1.3.2 Host Processor Interface to the PBIST Controller Registers

The Cortex-R4F CPU can select the algorithm and RAM groups for the memories' self-test from the on-chip ROM based on the application requirements. Once the self-test has executed, the CPU can query the PBIST controller registers to identify any memories that failed the self-test and to then take appropriate next steps as required by the application's author.

7.1.3.3 Memory Data Path

This is the read and write data path logic between different system and peripheral memories tightly coupled to the PBIST memory interface. The PBIST controller executes each selected algorithm on each valid memory group sequentially until all the algorithms are executed.

NOTE: Not all algorithms are designed to run on all RAM groups. If an algorithm is selected to run on an incompatible memory, this will result in a failure. Refer to [Table 2-5](#) and [Table 2-6](#) for RAM grouping and algorithm information.

7.2 RAM Grouping and Algorithm

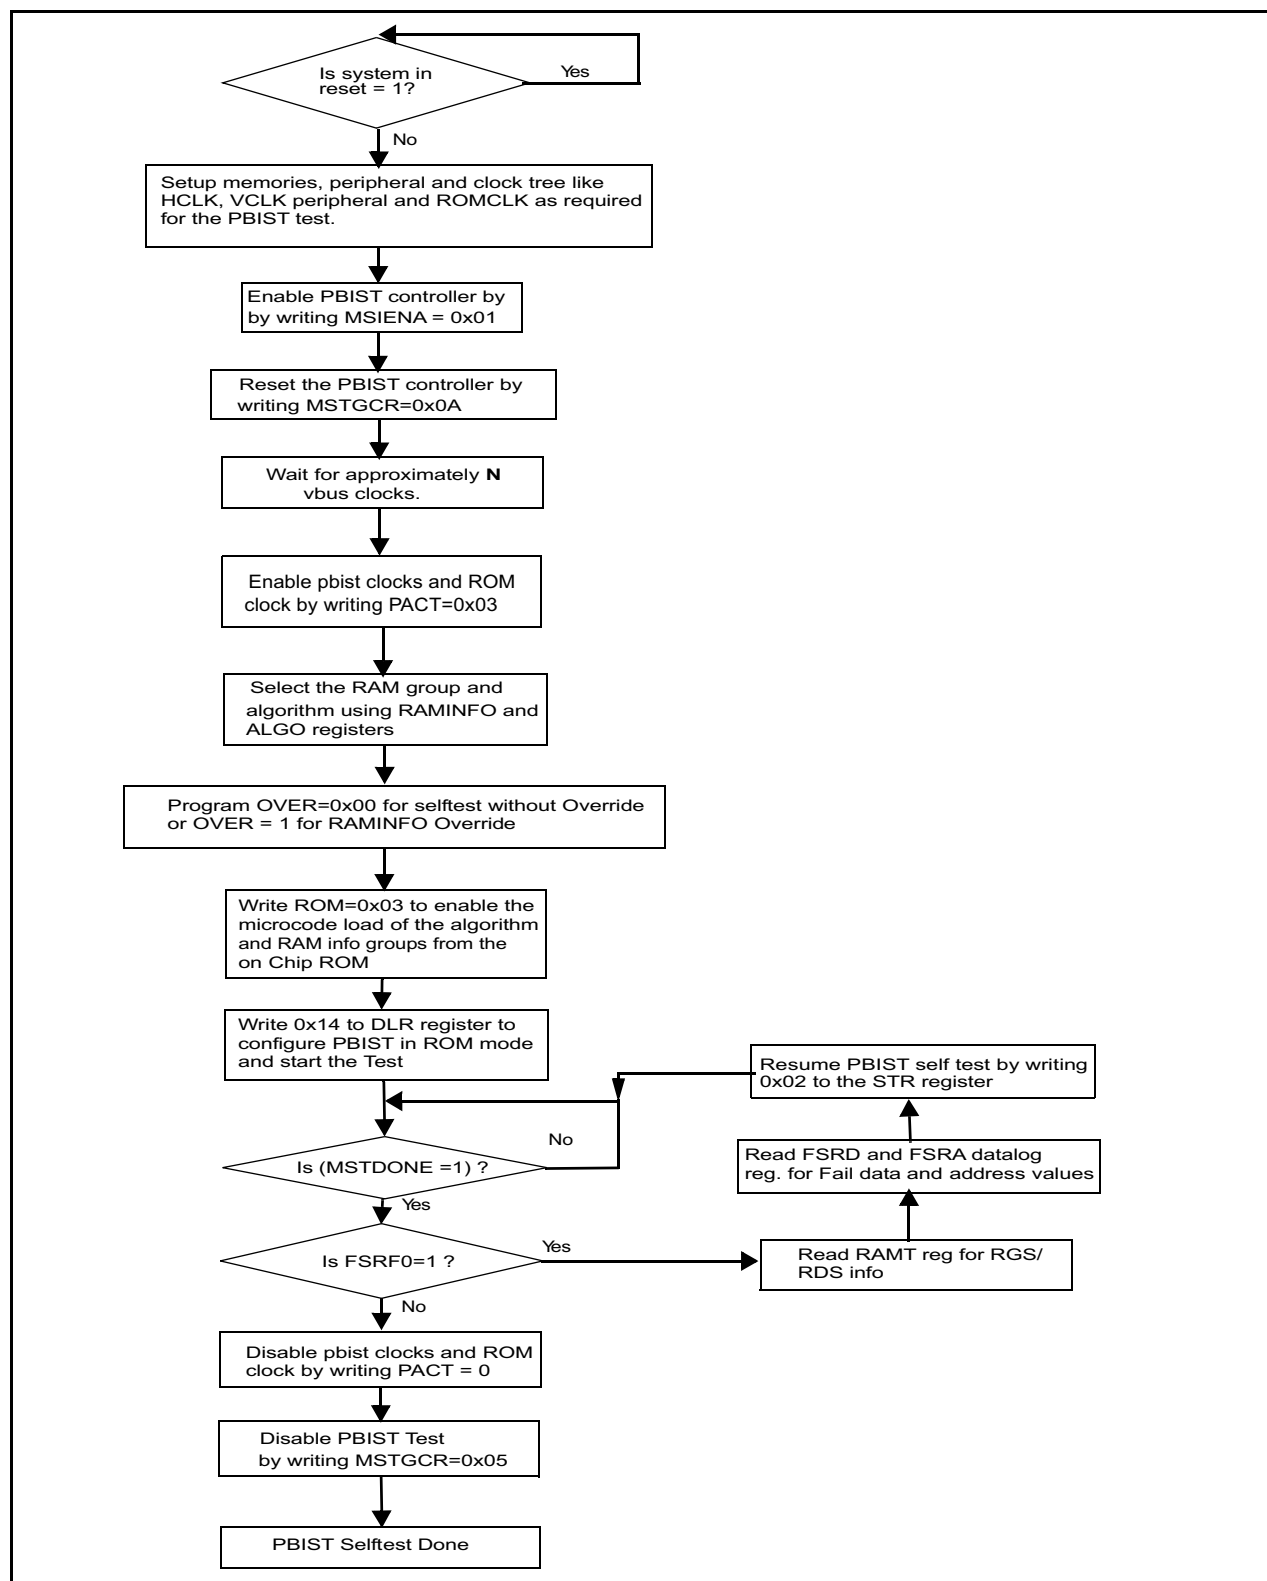

[Table 2-5](#) gives the list of RAM groups and their types supported on the device. [Table 2-6](#) maps the different algorithms supported in application mode for the RAM groups with the background patterns used for the particular algorithm.

NOTE: March13 is the most recommended algorithm for the memory self-test.

7.3 PBIST Flow

Figure 7-2 illustrates the memory self-test flow.

Figure 7-2. PBIST Memory Self-Test Flow Diagram

7.3.1 PBIST Sequence

1. Configure the device clock sources and domains so that they are running at their target frequencies.
2. Program the HCLK to PBIST ROM clock ratio by configuring the ROM_DIV field (bits 9:8) of the MSTGCR register of the system module. Check the device datasheet for the maximum supported PBIST ROM clock frequency.
3. Enable PBIST Controller by setting bit 1 of MSIENA register in system module.
4. Enable the PBIST self-test by writing a value of 0x0A to bits 3:0 of the MSTGCR in the system module.
5. Wait for N VBUS clock cycles based on the HCLK to PBIST ROM clock ratio:
 N = 16 when HCLK:PBIST ROM clock is 1:1
 N = 32 when HCLK:PBIST ROM clock is 1:2
 N = 64 when HCLK:PBIST ROM clock is 1:4
 N = 64 when HCLK:PBIST ROM clock is 1:8
6. Write 3h to PACT register to enable the PBIST internal clocks and ROM interface clock.
7. Program the ALGO register to decide which algorithm from the instruction ROM must be selected (the default value of ALGO register is all 1's, meaning all algorithms are selected). Similarly, program the RINFOL and RINFOU registers to indicate whether a particular RAM group in the instruction ROM would get executed or not.

NOTE: In case of RAM Override (Override Register (OVER) = 00), the user should make sure that only the algorithms that run on similar RAMs are selected. If a single port algorithm is selected in ROM Algorithm Mask Register (ALGO), the RAM Info Mask Lower Register (RINFOL) and RAM Info Mask Upper Register (RINFOU) must select only the single port RAM's. The same applies for two port RAM's. Check [Table 2-5](#) for information on the memory types.

8. Program OVER = 1h to run PBIST self-test without RAM override. Program OVER = 0 to run PBIST self-test with RAM Override.
9. Write a value of 3h to the ROM mask register should the microcode for the Algorithms as well as the RAM groups loaded from the on chip PBIST ROM.
10. Write DLR (Data Logger register) with 14h to configure the PBIST run in ROM mode and to enable the configuration access. This starts the memory self-tests.
11. Wait for the PBIST self-test done by polling MSTDONE bit of MSTCGSTAT register in System Module.
12. Once self-test is completed, check the Fail Status register FSRF0.
 In case there is a failure (FSRF0 = 1h)
 - (a) Read RAMT register which indicates the RGS and RDS values of the failure RAM
 - (b) Read FSRC0 and FSRC1 registers which contains the failure count
 - (c) Read FSRA0 and FSRA1 registers which contains the address of first failure
 - (d) Read FSRDL0 and FSRDL1 registers which contains the failure data.
 - (e) Write a value of 2h to the STR register to resume the test.
 In case there is no failure (FSRF0 = 0) the memory self-test is completed.
 - (a) Disable the PBIST internal and ROM clocks by writing a 0 to the PACT register.
 - (b) Disable the PBIST self-test by writing a value of 5h to bits 3:0 of the MSTGCR in the system module
 Repeat steps 2 through 9 for subsequent runs with different RAM group and algorithm configurations.
13. After required Memory tests are completed, Resume or Start the Normal Application software.

NOTE: The contents of the selected memory before the test will be completely lost. User software must take care of data backup if required. Typically the PBIST tests are carried out at the beginning of Application software.

NOTE: Memory test fail information is reported in terms of RGS:RDS and not RAM GROUP. Check [Table 2-5](#) for information on the RGS:RDS information applicable to each memory being tested.

7.4 Memory Test Algorithms on the On-chip ROM

This section provides a brief description for some of the test algorithms used for memory self-test.

1. March13N:

- March13N is the baseline test algorithm for SRAM testing. It provides the highest overall coverage. The other algorithms provide additional coverage of otherwise missed boundary conditions of the SRAM operation.
- The concept behind the general march algorithm is to indicate:
 - The bit cell can be written and read as both a 1 and a 0.
 - The bits around the bit cell do not affect the bit cell.
- The basic operation of the march is to initialize the array to a know pattern, then march a different pattern through the memory.
- Type of faults detected by this algorithm:
 - Address decoder faults
 - Stuck-At faults
 - Coupled faults
 - State coupling faults
 - Parametric faults
 - Write recovery faults
 - Read/write logic faults

2. Map Column:

- The MAP COLUMN algorithm is used to identify bit line sensitivities in the memory array. The memory array is loaded with a row stripe pattern of all 1s in the first row followed by all 0s in the second row and repeated throughout the array. Then the values are read down each column on consecutive cycles. The pattern in memory is inverted and run the column reads again.
- This particular pattern is looking for the following SRAM failure mechanisms:
 - Leakage due to a low resist path in a bit
 - An Open in the bit cell
 - Leakage on a BIT or BITN line
 - Miss-balance in the sense amp
 - Leakage in the sense
 - High resist in the sense amp
 - Failure of the pre-charge circuits after read operations

3. Pre-Charge:

- The Pre-Charge algorithm exercises the pre-charge capability within the SRAM array. It is important to specifically target this issue as it is the only part of the analog portion of the SRAM that is frequency sensitive.
- Similar to the MAP COLUMN algorithm, this algorithm works its way down the columns of the SRAM. However, unlike the MAP COLUMN, this algorithm sandwiches a write between two reads to force the worst-case conditions for the pre-charge circuits in the array.
- This test will fail when an increase in system frequency nears the minimum access time of the array, at this boundary:
 - High voltage should operate better than low voltage.
 - Likewise, low temperature should operate better than high temperature.

4. DOWN1a:

- The Down1 pattern forces the switching of all data bits and most address bits on consecutive read cycles. This is primarily a read/write test of the CPU/memory subsystem.
- The aggressive writes target at-speed write failures.
- It also targets row/column decode in the memory array.
- Targets the sense amps and sense amp multiplexors.
- Memory array output buffers.
- This algorithm operates as follows:
 - Load 1st half of the memory under test with one pattern.
 - Load 2nd half of the memory under test with the bit-wise inverse of the pattern.
 - Alternate sequential reads sequences between one sequence starting at the beginning of the array and a second sequence starting at the end of the array.
 - Upon completion of the read back, invert the patterns in both halves of the array and repeat the above step.
 - Perform an aggressive write sequence by alternating writes between the bottom half of the memory upwards with a data pattern and the top half of the memory downwards with the inverse data pattern.
 - Invert the data pattern for the above two steps to perform another sequence of aggressive writes.

5. DTXN2a:

This algorithm is used to target the global column decode Logic.

7.5 PBIST Control Registers

PBIST controller uses configuration registers for programming the algorithm and its execution. All the configuration registers are memory mapped for access by the CPU through the Peripheral Bus interface. The base address for the control registers is FFFF E400h.

NOTE: There is no watchdog functionality implemented in the PBIST controller. If a bad code is executed, the PBIST will run forever. The PBIST controller does not guard against this situation.

Registers are accessible only when the clock to PBIST controller is active. The clock is activated by first writing 0x3 to PACT register.

Table 7-1. PBIST Registers

| Offset | Acronym | Register Description | Section |
|-------------|----------|--|--------------------------------|
| 000h - 15Ch | Reserved | Reserved locations. Do not write to these locations. | |
| 160h | RAMT | RAM Configuration Register | Section 7.5.1 |
| 164h | DLR | Datalogger Register | Section 7.5.2 |
| 168h - 17Ch | Reserved | Reserved locations. Do not write to these locations. | |
| 180h | PACT | PBIST Activate/ROM Clock Enable Register | Section 7.5.3 |
| 184h | PBISTID | PBIST ID Register | Section 7.5.4 |
| 188h | OVER | Override Register | Section 7.5.5 |
| 190h | FSRF0 | Fail Status Fail Register 0 | Section 7.5.6 |
| 198h | FSRC0 | Fail Status Count Register 0 | Section 7.5.7 |
| 19Ch | FSRC1 | Fail Status Count Register 1 | Section 7.5.7 |
| 1A0h | FSRA0 | Fail Status Address 0 Register | Section 7.5.8 |
| 1A4h | FSRA1 | Fail Status Address 1 Register | Section 7.5.8 |
| 1A8h | FSRDL0 | Fail Status Data Register 0 | Section 7.5.9 |
| 1B0h | FSRDL1 | Fail Status Data Register 1 | Section 7.5.9 |
| 1C0h | ROM | ROM Mask Register | Section 7.5.10 |
| 1C4h | ALGO | ROM Algorithm Mask Register | Section 7.5.11 |
| 1C8h | RINFOL | RAM Info Mask Lower Register | Section 7.5.12 |
| 1CCh | RINFOU | RAM Info Mask Upper Register | Section 7.5.13 |

7.5.1 RAM Configuration Register (RAMT)

This register is divided into the following internal registers, none of which have a default value after reset. [Figure 7-3](#) and [Table 7-2](#) illustrate this register.

This register provides the information regarding the memory being currently tested. In case of a PBIST failure, the application can read this register to identify the RGS:RDS values for the memory that failed the self-test.

Figure 7-3. RAM Configuration Register (RAMT) [offset = 0160h]

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 7-2. RAM Configuration Register (RAMT) Field Descriptions

| Bit | Field | Description |
|-------|-------|---|
| 31-24 | RGS | Ram Group Select. Refer to Table 2-5 for information on the RGS value for each memory. |
| 23-16 | RDS | Return Data Select. Refer to Table 2-5 for information on the RDS values for each memory. |
| 15-8 | DWR | Data Width Register |
| 7-6 | SMS | Sense Margin Select Register |
| 5-2 | PLS | Pipeline Latency Select |
| 1-0 | RLS | RAM Latency Select |

7.5.2 Datalogger Register (DLR)

This register puts the PBIST controller into the appropriate comparison modes for data logging. [Figure 7-4](#) and [Table 7-3](#) illustrate this register.

Figure 7-4. Datalogger Register (DLR) [offset = 0164h]

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 7-3. Datalogger Register (DLR) Field Descriptions

| Bit | Field | Value | Description |
|------|----------|-------|---|
| 31-5 | Reserved | 0 | Reads return 0. Do not change these bits from their default value. |
| 4 | DLR4 | | Config access: setting this bit allows the host processor to configure the PBIST controller registers |
| 3 | Reserved | 1 | Do not change this bit from its default value of 1. |
| 2 | DLR2 | | ROM-based testing: setting this bit enables the PBIST controller to execute test algorithms that are stored in the PBIST ROM. |
| 1-0 | Reserved | 00 | Do not change these bits from their default value of 00. |

- DLR2: ROM-based testing mode**

Writing a 1 to this register starts the ROM-based testing. This register is used to initiate ROM-based testing from Config and ATE interfaces. Also, since a 1 in this bit position means the instruction ROM is used for memory testing, all the intermediate interrupts and PBIST done signal after each memory test are masked until all the selected algorithms in the ROM are executed for all RAM groups. However, a failure would stop the test and report the status immediately.

- DLR4: Config access mode**

This mode, when set, indicates the CPU is being used to access PBIST.

7.5.3 PBIST Activate/ROM Clock Enable Register (PACT)

This is the first register that needs to be programmed to activate the PBIST controller. Bit [0] is used for static clock gating, and unless a 1 is written to this bit, all the internal PBIST clocks are shut off. [Figure 7-5](#) and [Table 7-4](#) illustrate this register.

NOTE: This register must be programmed to 3h during application self-test.

Figure 7-5. PBIST Activate/ROM Clock Enable Register (PACT) [offset = 0180h]

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 7-4. PBIST Activate/ROM Clock Enable Register (PACT) Field Descriptions

| Bit | Field | Value | Description |
|------|----------|-------|--|
| 31-1 | Reserved | 0 | Read returns 0. Writes have no effect. |
| 0 | PACT0 | 0 | ROM Clock Enable Register |
| | | 0 | Disable internal PBIST clocks |
| | | 1 | Enable internal PBIST clocks |

• PACT0

This bit must be set to turn on internal PBIST clocks. Setting this bit asserts an internal signal that is used as the clock gate enable. As long as this bit is 0, any access to PBIST will not go through, and PBIST will remain in an almost zero-power mode.

7.5.4 PBIST ID Register

Functionality of this register is described in [Figure 7-6](#) and [Table 7-5](#).

Figure 7-6. PBIST ID Register [offset = 184h]

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 7-5. PBIST ID Register Field Descriptions

| Bit | Field | Value | Description |
|------|----------|-------|--|
| 31-8 | Reserved | 0 | Reads return 0. Writes have no effect. |
| 7-0 | PBIST ID | | This is a unique ID assigned to each PBIST controller in a device with multiple PBIST controllers. |

7.5.5 Override Register (OVER)

Functionality of the register is described in [Figure 7-7](#) and [Table 7-6](#).

Figure 7-7. Override Register (OVER) [offset = 0188h]

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 7-6. Override Register (OVER) Field Descriptions

| Bit | Field | Value | Description |
|------|----------|-------|--|
| 31-3 | Reserved | 0 | Read returns 0. Writes have no effect. |
| 2 | Reserved | 0 | Reserved. This bit must not be changed from its default value of 0. |
| 1 | Reserved | 0 | Reserved. This bit must not be changed from its default value of 0. |
| 0 | OVER0 | 0 | RINFO Override Bit The RAM info registers RINFOL and RINFOU are used to select the memories for test |
| | | 1 | The memory information available from ROM will override the RAM selection from the RAM info registers RINFOL and RINFOU. |

• OVER0

While doing ROM-based testing, each algorithm downloaded from the ROM has a memory mask associated with it that defines the applicable memory groups the algorithm will be run on. By default, this bit is set to 1, which means the memory mask that is downloaded from the ROM will overwrite the RAM info registers. The override bit can be reset by writing a 0 to it. In this case, the application can select the RAM groups to be tested by configuring the RAM info registers.

NOTE: When this override bit = 0, each algorithm selected in ALGO register will run on each RAM selected in RINFOL and RINFOU register. It must be ensured that:

1. Only the same type of memories (single port or two port) are selected, and
2. Only memories that are valid for all algorithms enabled via the ALGO register are selected.

If the above two requirements are not met, the memory self-test will fail.

7.5.6 Fail Status Fail Register (FSRF0)

This register indicates if a Port0 failure occurred during a memory self-test. Bit [0] gets set whenever a failure occurs. Functionality of the register is described in [Figure 7-8](#) and [Table 7-7](#).

Figure 7-8. Fail Status Fail Register 0 (FSRF0) [offset = 0190h]

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 7-7. Fail Status Fail Register 0 (FSRF0) Field Descriptions

| Bit | Field | Value | Description |
|------|----------|-------|---|
| 31-1 | Reserved | 0 | Read returns 0. Writes have no effect. |
| 0 | FSRF0 | 0 | Fail Status 0. This bit would be cleared by reset of the module using MSTGCR register in system module. |
| | | 1 | No Failure Occurred |
| | | 1 | Indicates a failure on Port 0 |

7.5.7 Fail Status Count Registers (FSRC0 and FSRC1)

These registers keep count of the number of failures observed during the memory self-test. The PBIST controller stops executing the memory self-test whenever a failure occurs in any memory instance for any of the test algorithms. The value in FSRC0 / FSRC1 gets incremented by one whenever a failure occurs and gets decremented by one when the failure is processed. FSRC0 is for Port 0 and FSRC1 is for Port 1. [Figure 7-9](#) and [Table 7-8](#) illustrate the FSRC0 register, while [Figure 7-10](#) and [Table 7-9](#) illustrate the FSRC1 register.

Figure 7-9. Fail Status Count 0 Register (FSRC0) [offset = 0198h]

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 7-8. Fail Status Count 0 Register (FSRC0) Field Descriptions

| Bit | Field | Value | Description |
|------|----------|-------|--|
| 31-8 | Reserved | 0 | Reads return 0. Writes have no effect. |
| 7-0 | FSRC0 | | Fail Status Count 0. Indicates the number of failures on port 0. |

Figure 7-10. Fail Status Count Register 1 (FSRC1) [offset = 019Ch]

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 7-9. Fail Status Count Register 1 (FSRC1) Field Descriptions

| Bit | Field | Value | Description |
|------|----------|-------|--|
| 31-8 | Reserved | 0 | Reads return 0. Writes have no effect. |
| 7-0 | FSRC1 | | Fail Status Count 1. Indicates the number of failures on port 1. |

7.5.8 Fail Status Address Registers (FSRA0 and FSRA1)

These registers capture the memory address of the first failure on port 0 and port 1, respectively. [Figure 7-11](#) and [Table 7-10](#) illustrate the FSRA0 register, while [Figure 7-12](#) and [Table 7-11](#) illustrate the FSRA1 register.

Figure 7-11. Fail Status Address 0 Register (FSRA0) [offset = 01A0h]

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 7-10. Fail Status Address 0 Register (FSRA0) Field Descriptions

| Bit | Field | Value | Description |
|-------|----------|-------|---|
| 31-16 | Reserved | 0 | Read returns 0. Writes have no effect. |
| 15-0 | FSRA0 | | Fail Status Address 0. Contains the address of the first failure. |

Figure 7-12. Fail Status Address 1 Register (FSRA1) [offset = 01A4h]

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 7-11. Fail Status Address 1 Register (FSRA1) Field Descriptions

| Bit | Field | Value | Description |
|-------|----------|-------|---|
| 31-16 | Reserved | 0 | Read returns 0. Writes have no effect. |
| 15-0 | FSRA1 | | Fail Status Address 1. Contains the address of the first failure. |

7.5.9 Fail Status Data Registers (FSRDL0 and FSRDL1)

These registers are used to capture the failure data in case of a memory self-test failure. FSRDL0 corresponds to Port 0, while FSRDL1 corresponds to Port 1. [Figure 7-13](#) and [Table 7-12](#) illustrate the FSRDL0 register, while [Figure 7-14](#) and [Table 7-13](#) illustrate the FSRDL1 register.

Figure 7-13. Fail Status Data Register 0 (FSRDL0) [offset = 01A8h]

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 7-12. Fail Status Data Register 0 (FSRDL0) Field Descriptions

| Bit | Field | Description |
|------|--------|------------------------|
| 31-0 | FSRDL0 | Failure data on port 0 |

Figure 7-14. Fail Status Data Register 1 (FSRDL1) [offset = 01B0h]

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 7-13. Fail Status Data Register 1 (FSRDL1) Field Descriptions

| Bit | Field | Description |
|------|--------|------------------------|
| 31-0 | FSRDL1 | Failure data on port 1 |

7.5.10 ROM Mask Register (ROM)

This two-bit register sets appropriate ROM access modes for the PBIST controller. The default value is 11b. This register is illustrated in [Figure 7-15](#). It can be programmed according to [Table 7-14](#).

Figure 7-15. ROM Mask Register (ROM) [offset = 01C0h]

| | | | | | | | | | | | | | | | |
|-----|----------|--|--|--|--|--|--|--|--|--|--------|---|---|--|----|
| 31 | Reserved | | | | | | | | | | | | | | 16 |
| R-0 | | | | | | | | | | | | | | | |
| 15 | Reserved | | | | | | | | | | 2 | 1 | 0 | | |
| R-0 | | | | | | | | | | | ROM | | | | |
| | | | | | | | | | | | R/W-3h | | | | |

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 7-14. ROM Mask Register (ROM) Field Descriptions

| Bit | Field | Value | Description |
|------|----------|-------|--|
| 31-2 | Reserved | 0 | Read returns 0. Writes have no effect. |
| 1-0 | ROM | 0 | No information is used from ROM |
| | | 1h | Only RAM Group information from ROM |
| | | 2h | Only Algorithm information from ROM |
| | | 3h | Both Algorithm and RAM information from ROM. This option should be selected for application self-test. |

7.5.11 ROM Algorithm Mask Register (ALGO)

This register is used to indicate the algorithm(s) to be used for the memory self-test routine. Each bit corresponds to a specific algorithm. For example, bit [0] controls whether algorithm 1 is enabled or not. [Figure 7-16](#) and [Table 7-15](#) illustrate this register.

Figure 7-16. ROM Algorithm Mask Register (ALGO) [offset = 01C4h]

| | | | | | | | | | | | | | | | | | | | | | | | |
|---------|--|--|--|--|--|--|--|--|--|--|---------|----|--|--|--|--|--|--|--|--|--|--|----|
| 31 | | | | | | | | | | | 24 | 23 | | | | | | | | | | | 16 |
| ALGO3 | | | | | | | | | | | ALGO2 | | | | | | | | | | | | |
| R/W-FFh | | | | | | | | | | | R/W-FFh | | | | | | | | | | | | |

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 7-15. Algorithm Mask Register (ALGO) Field Descriptions

| Bit | Field | Value | Description |
|------|-------|-------|-------------------------------------|
| 31 | | 0 | Algorithm 32 is not selected |
| | | 1 | Selects algorithm 32 for PBIST run |
| 30 | | 0 | Algorithm 31 is not selected |
| | | 1 | Selects algorithm 31 for PBIST run |
| : | | | |
| 0 | | 0 | Algorithm 1 is not selected |
| | | 1 | Selects algorithm 1 for PBIST run |
| 31-0 | | 0 | None of the algorithms are selected |

NOTE: Please refer to [Table 2-6](#) for available algorithms and the memories on which each algorithm can be run.

7.5.12 RAM Info Mask Lower Register (RINFOL)

This register is to select RAM groups to run the algorithms selected in the ALGO register. For an algorithm to be executed on a particular RAM group, the corresponding bit in this register must be set to 1. The default value of this register is all 1s, which means all the RAM Groups are selected. [Figure 7-17](#) and [Table 7-16](#) illustrate this register.

The information from this register is used only when bit 0 in OVER register is not set.

Figure 7-17. RAM Info Mask Lower Register (RINFOL) [offset = 01C8h]

| | | | |
|---------|----|---------|----|
| 31 | 24 | 23 | 16 |

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 7-16. RAM Info Mask Lower Register (RINFOL) Field Descriptions

| Bit | Field | Value | Description |
|------|-------|-------|---|
| 31 | | 0 | RAM Group 32 is not selected |
| | | 1 | Selects group 32 for PBIST run |
| 30 | | 0 | RAM Group 31 is not selected |
| | | 1 | Selects RAM group 31 for PBIST run |
| : | | | |
| 0 | | 0 | RAM Group 1 is not selected |
| | | 1 | Selects RAM Group 1 for PBIST run |
| 31-0 | | 0 | None of the RAM Groups 1 to 32 are selected |

NOTE: Please refer to [Table 2-5](#) for RAM info groups.

7.5.13 RAM Info Mask Upper Register (RINFOU)

This register is to select RAM groups to run the algorithms selected in the ALGO register. For an algorithm to be executed on a particular RAM group, the corresponding bit in this register should be set to 1. The default value of this register is all 1s, which means all the RAM Info Groups would be selected. [Figure 7-18](#) and [Table 7-17](#) illustrate this register.

Figure 7-18. RAM Info Mask Upper Register (RINFOU) [offset = 01CCh]

| | | | |
|---------|----|---------|----|
| 31 | 24 | 23 | 16 |
| RINFOU3 | | RINFOU2 | |
| R/W-FFh | | R/W-FFh | |

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 7-17. RAM Info Mask Upper Register (RINFOU) Field Descriptions

| Bit | Field | Value | Description |
|------|-------|-------|--|
| 31 | | 0 | RAM Group 64 is not selected |
| | | 1 | Selects group 64 for PBIST run |
| 30 | | 0 | RAM Group 63 is not selected |
| | | 1 | Selects RAM group 63 for PBIST run |
| : | | | |
| 0 | | 0 | RAM Group 33 is not selected |
| | | 1 | Selects RAM Group 33 for PBIST run |
| 31-0 | | 0 | None of RAM Groups 33 to 64 are selected |

7.6 PBIST Configuration Example

The following examples assume that the PLL is locked and selected as clock source with HCLK = 160 MHz and VCLK = 80 MHz.

7.6.1 Example 1 : Configuration of PBIST Controller to Run Self-Test on RAM Group 3

This example explains the configurations for running March13, Down1A and Map Column algorithms on RAM Group 3 (see device datasheet for RAM Group information).

1. Program the HCLK to PBIST ROM clock ratio to 1:2 in System Module.
MSTGCR[9:8] = 1
2. Enable PBIST Controller in System Module.
MSIENA[31:0] = 0x00000001
3. Enable the PBIST self-test in System Module.
MSTGCR[3:0] = 0xA
4. Wait for at least 32 VCLK cycles in a software loop.
5. Enable the Pbist internal clocks and ROM interface clock.
PACT = 0x3
6. Disable RAM Override. This will make the PBIST controller use the information provided by the application in the RINFOx and ALGO registers for the memory self-test.
OVER = 0x0
7. Select the Algorithm (refer to [Table 2-6](#)).
ALGO = 0x00000054 (Algo 3 = March13N, Algo 5 = down1A_red, Algo 7 = Map column for two-port RAM Group 3)
8. Program the RAM group Info to select RAM Group 3 (refer to [Table 2-5](#)).
RINFOL = 0x00000004 (select RAM Group 3)
RINFOU = 0x00000000 (since this device supports only 28 RAM Groups)
9. Select both Algorithm and RAM information from on chip PBIST ROM.
ROM = 0x3
10. Configure PBIST to run in ROM Mode and start PBIST run.
DLR = 0x14
11. Wait for PBIST test to complete by polling MSTDONE bit in System Module.
while (MSTDONE != 1)
12. Once self-test is completed, check the Fail Status register FSRF0.
 - (a) In case there is a failure (FSRF0 = 0x01):
 - (i) Read RAMT register that indicates the RGS and RDS values of the failure RAM.
 - (ii) Read FSRC0 and FSRC1 registers that contains the failure count.
 - (iii) Read FSRA0 and FSRA1 registers that contains the address of first failure.
 - (iv) Read FSRDL0 and FSRDL1 registers that contains the failure data.
 - (v) Resume the Test if required using Program Control register (offset = 0x16C) STR = 2.
 - (b) In case there is no failure (FSRF0 = 0x00), the memory self-test is completed:
 - (i) Disable the PBIST internal and ROM clocks.
PACT = 0
 - (ii) Disable the PBIST self-test.
MSTGCR[3:0] = 0x5

7.6.2 Example 2 : Configuration of PBIST Controller to Run Self-Test on ALL RAM Groups

This example explains the configurations for running March13, Down1A and Mapcolumn algorithms on all RAM groups defined in the PBIST ROM.

1. Program the HCLK to PBIST ROM clock ratio to 1:2 in System Module.
MSTGCR[9:8] = 1
2. Enable PBIST Controller in System Module.
MSIENA[31:0] = 0x00000001
3. Enable the PBIST self-test in System Module.
MSTGCR[3:0] = 0xA
4. Wait for at least 32 VCLK cycles in a software loop.
5. Enable the Pbist internal clocks and ROM interface clock.
PACT = 0x3
6. Enable RAM Override.
OVER = 0x1
7. Select the Algorithms to be run (refer to [Table 2-6](#)).
ALGO = 0x000000FC (select March13N, Down1A and Map Column algorithms for single-port and two-port RAMs)
8. Select both Algorithm and RAM information from on chip PBIST ROM.
ROM = 0x3
9. Configure PBIST to run in ROM Mode and kickoff PBIST test.
DLR = 0x14
10. Wait for PBIST test to complete by polling MSTDONE bit in System Module.
while (MSTDONE !=1)
11. Once self-test is completed, check the Fail Status register FSRF0:
 - (a) In case there is a failure (FSRF0 = 0x01):
 - (i) Read RAMT register that indicates the RGS and RDS values of the failure RAM.
 - (ii) Read FSRC0 and FSRC1 registers that contains the failure count.
 - (iii) Read FSRA0 and FSRA1 registers that contains the address of first failure.
 - (iv) Read FSRDL0 and FSRDL1 registers that contains the failure data.
 - (v) Resume the Test if required using Program Control register (offset = 0x16C) STR = 2.
 - (b) In case there is no failure (FSRF0 = 0x00), the memory self-test is completed:
 - (i) Disable the PBIST internal and ROM clocks.
PACT = 0
 - (ii) Disable the PBIST self-test.
MSTGCR[3:0] = 0x5

CPU Self-Test Controller (STC) Module

This chapter describes the basics and configuration of the CPU self-test controller present in the device.

| Topic | Page |
|--|------------|
| 8.1 General Description | 361 |
| 8.2 Application Self-Test Flow | 363 |
| 8.3 STC Test Coverage and Duration..... | 365 |
| 8.4 STC Control Registers | 366 |
| 8.5 STC Configuration Example | 375 |

8.1 General Description

The CPU self-test controller (STC) is used to test the ARM-CPU core using the Deterministic Logic Built-in Self-Test (LBIST) Controller as the test engine. To achieve better coverage for the self-test of complex cores like Cortex-R4, on-chip logic BIST is the preferred solution.

8.1.1 CPU Self-Test Controller Features

The CPU self-test controller has the following features:

- Capable of running the complete test as well as running a few intervals at a time
 - Ability to continue from the last executed interval (test set) as well as the ability to restart from the beginning (first test set)
 - Total of 24 intervals supported in this device
- Complete isolation of the self-tested CPU core from the rest of the system during the self-test run
 - The self-tested CPU core master bus transaction signals are configured to be in idle mode during the self-test run
 - Any master access to the CPU core under self-test (example: DMA access to CPU TCM) will be held until the completion of the self-test
- Ability to capture the failure interval number
- Timeout counter for the CPU self-test run as a fail-safe feature
- Able to read the MISR data (shifted from LBIST controller) of the last executed interval of the self-test run for debugging purposes
- STCCLK determines the self-test execution speed, STC clock divider (STCCLKDIV) register in the system module is used to divide HCLK (system clock) to generate STCCLK

8.1.2 STC Block Diagram

STC module provides an interface to the LBIST controller implemented on the core.

The CPU STC is composed of following blocks of logic:

- ROM Interface
- FSM and Sequence Control
- Register Block
- Peripheral Bus Interface (VBUSP Interface)
- STC Bypass/ATE Interface

8.1.2.1 ROM Interface

This block handles the ROM address and control signal generation to read the self-test microcode from the ROM. The test microcode and golden signature value for each interval are stored in ROM.

8.1.2.1.1 FSM and Sequence Control

This block generates the signals and data to the LBIST controller based on the seed, test_type and scan chain depth.

8.1.2.1.2 Clock Control

The CLOCK CNTRL sub-block handles the internal clock selection and clock generation for the ROM and LBIST controller.

8.1.2.2 Register Block

This block handles the control of the self-test controller. This block contains various configuration and status registers that provide the result of a self-test run. These registers are memory-mapped and accessible through the Peripheral Bus (VBUSP) Interface. This block controls the reseeding (reloading the existing seed of the PRPG) in the LBIST controller.

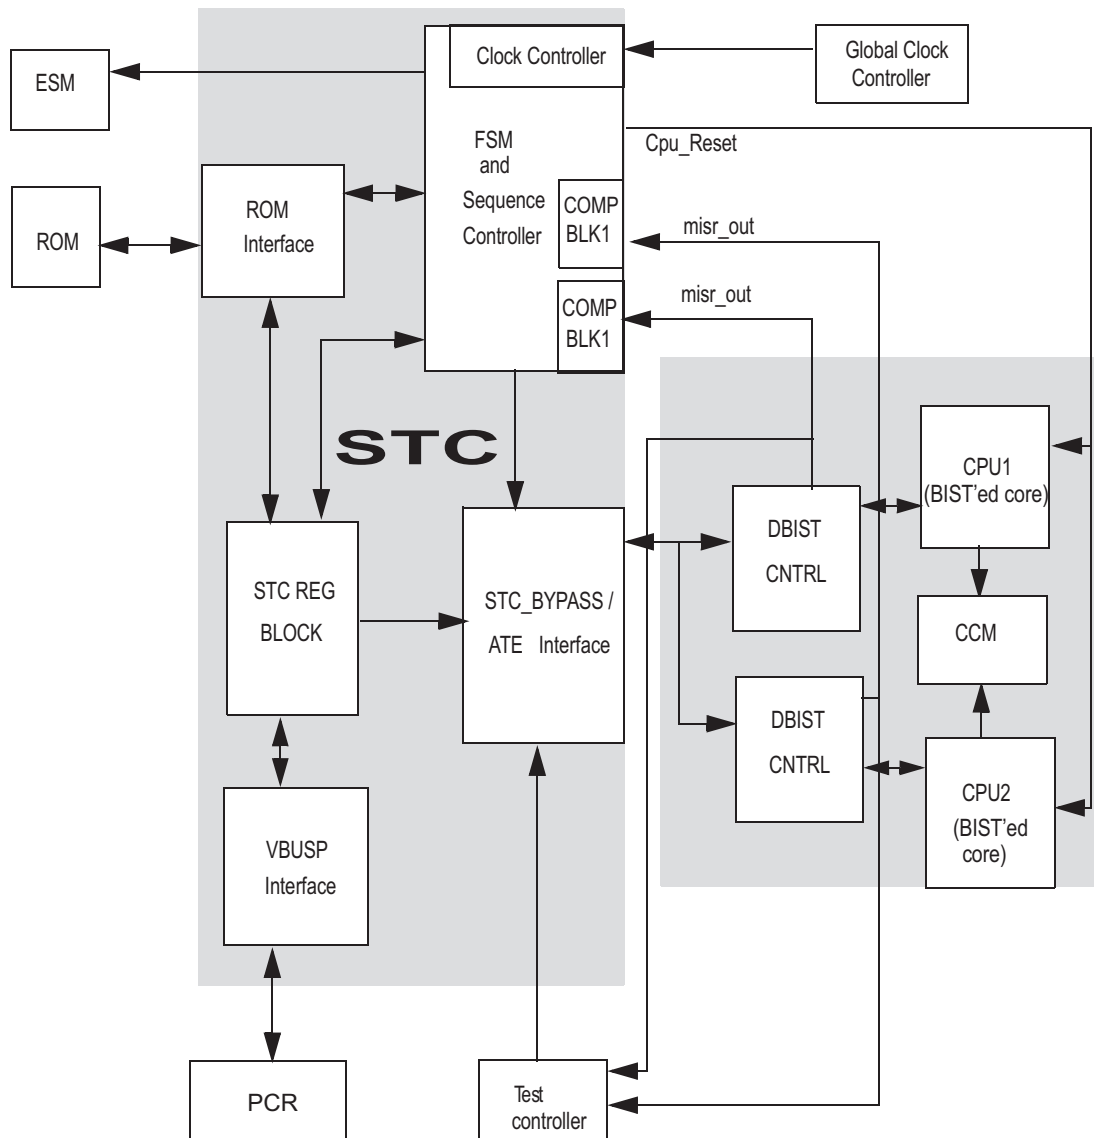

8.1.2.3 STC Bypass / ATE Interface

This is a production test interface. Only for TI internal use.

8.1.2.4 Peripheral Bus (VBUSP) Interface

STC control registers are accessed through Peripheral Bus (VBUSP) Interface. During application programming, configuration registers are programmed through the Peripheral Bus Interface to enable and run the self-test controller.

Figure 8-1. STC Block Diagram

8.2 Application Self-Test Flow

This section describes the STC module configuration and the application self-test flow that the user should follow for successful execution. The following two configurations must be part of the STC initialization code:

- STC clock rate configuration, STC clock divider (STCCLKDIV) register in system module is used to divide HCLK (system clock) to generate STCCLK
- Clear SYSESR register before triggering an STC test

8.2.1 STC Module Configuration

- Configure the test interval count using STCGCR0[31:16] register. A maximum of 24 intervals are supported in the device. You can run 24 intervals together or in slices. If the tests are run in slices, the user software can specify to the self-test controller whether to continue the run from the next interval onwards or to restart from interval 0 using bit STCGCR0[0]. This bit gets reset after the completion of the self-test run.
- Configure self-test run timeout counter preload register STCTPR. This register contains the total number of VBUS clock cycles it will take before a self-test timeout error (TO_ERR) will be triggered after the initiation of the self-test run.
- Enable CPU self-test by writing the enable key to STCGCR1 register.

8.2.2 Context Saving

STC generates a CPU reset after completion of the test regardless of pass or fail. You can run the STC test during startup or can divide STC into 24 or fewer intervals and run them during normal operation.

If STC is ran only on startup, the user software need not save the CPU contents since the reset caused will go through all startup configurations. You should check the STCGSTAT register for the self-test status before going to the application software.

If STC is divided into intervals and ran, user software must save the CPU contents and reload them after the CPU reset caused by the completion of the STC test interval. The check for STC status should bypass STC run if the reset is caused by an STC run to prevent a cyclic reset, that is, if reset is caused by STC the second time through, then it should not be ran again. You should also check the STCGSTAT register for the self-test status before restoring the application software.

Following are some of the registers that are required to be backed up before and restored after self-test:

1. CPU core registers (all modes R0-R15, PC, CPSR)
2. CP15 System Control Coprocessor registers - MPU control and configuration registers, Auxiliary Control Register used to Enable ECC, Fault Status Register etc.
3. CP13 Coprocessor Registers - FPU configuration registers, General Purpose Registers
4. Hardware Break Point and watch point registers like BVR, BSR, WVR, WSR etc.

For more information on the CPU reset, refer to the [ARM® Cortex®-R4F Technical Reference Manual](#).

NOTE: Check all reset source flags in the SYSESR register after a CPU BIST execution. If a flag, in addition to CPU reset, is set, clear the CPU reset flag and service the other reset sources accordingly.

8.2.3 Entering CPU Idle Mode

After enabling the STC test by writing the STC enable key, the test is triggered only after the CPU is taken to idle mode by executing the CPU Idle Instruction **asm(" WFI")**.

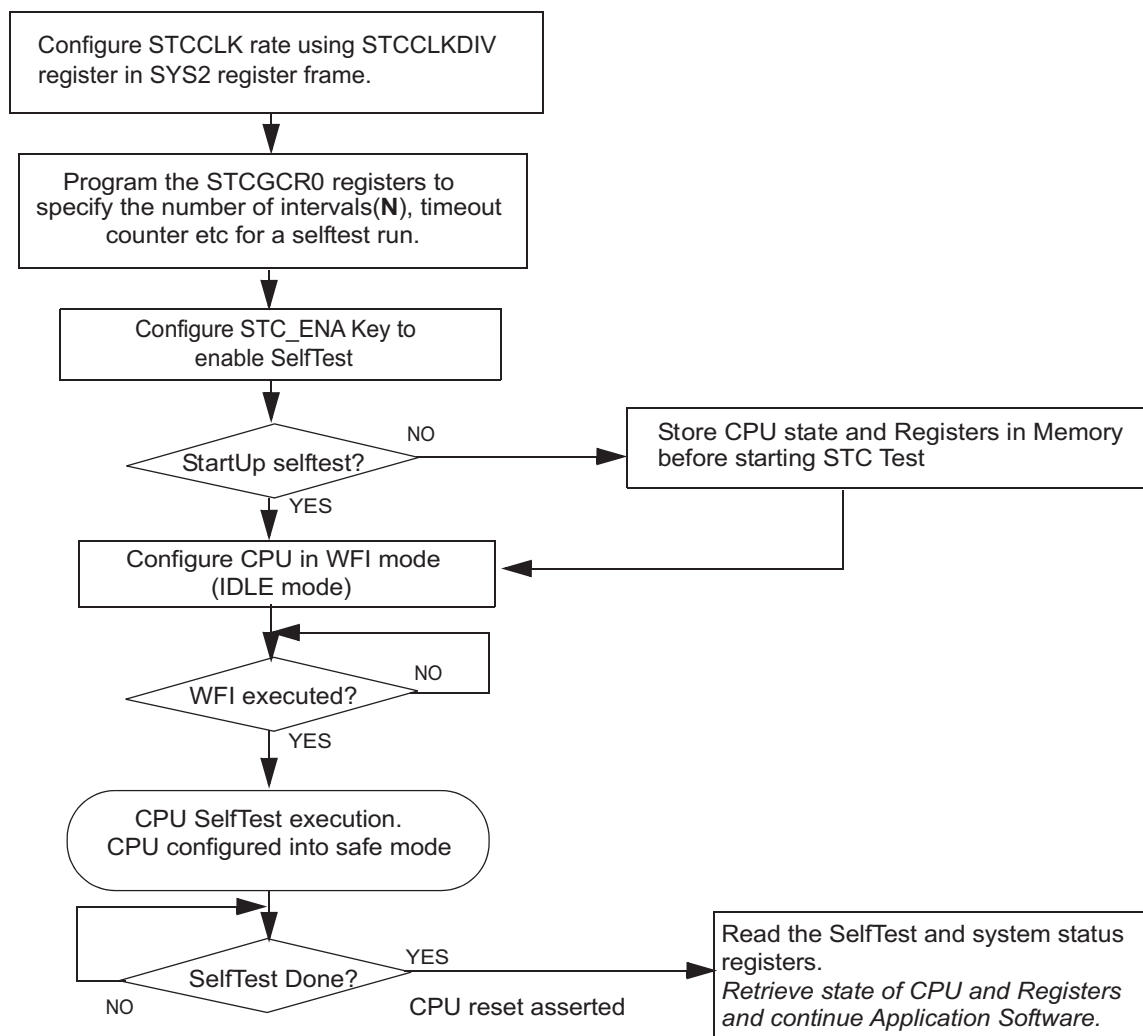

8.2.4 Self-Test Completion and Error Generation

At the end of each interval, the 128 bit MISR value (reflected in registers CPUx_CURMISR[3:0]) from the DBIST controller is shifted into the STC. This is compared with the golden MISR value stored in the ROM.

At the end of a CPU self-test, the STC controller updates the status flags in the Global Status Register (STCGSTAT) and resets the CPU. In case of a MISR mismatch or a test timeout, an error is generated through the ESM module. TEST_ERR signal is asserted when an MISR miss-compare occurs during the self-test. A TO_ERR is asserted when a timeout occurs during the self-test, meaning the test could not complete within the time specified in the timeout counter preload register STCTPR. However, at the device level, these two errors are combined and mapped to a single ESM channel. To identify which error occurred, user software must check the global status register (STCGSTAT) and fail status register STCFSTAT in the ESM interrupt service routine.

Figure 8-2 illustrates the application self-test test flow chart, drawn based on the assumption that the device has gone through startup, necessary clocks initialized and SYSESR register bits cleared.

Figure 8-2. Application Self-Test Flow Chart

8.3 STC Test Coverage and Duration

The test coverage and number of test execution cycles (STCCLK) for each test interval when the device is running at HCLK = 180 MHz, VCLK = 90 MHz, and STCCLK = 90 MHz are shown in [Table 8-1](#).

Table 8-1. STC Test Coverage and Duration

| Intervals | Test Coverage | Test Cycle | Test Time (μs) |
|-----------|---------------|------------|----------------|
| 0 | 0 | 0 | 0 |
| 1 | 62.13 | 1365 | 15.17 |
| 2 | 70.09 | 2730 | 30.33 |
| 3 | 74.49 | 4095 | 45.50 |
| 4 | 77.28 | 5460 | 60.67 |
| 5 | 79.28 | 6825 | 75.83 |
| 6 | 80.90 | 8190 | 91.00 |
| 7 | 82.02 | 9555 | 106.17 |
| 8 | 83.10 | 10920 | 121.33 |
| 9 | 84.08 | 12285 | 136.50 |
| 10 | 84.87 | 13650 | 151.67 |
| 11 | 85.59 | 15015 | 166.83 |
| 12 | 86.11 | 16380 | 182.00 |
| 13 | 86.67 | 17745 | 197.17 |
| 14 | 87.16 | 19110 | 212.33 |
| 15 | 87.61 | 20475 | 227.50 |
| 16 | 87.98 | 21840 | 242.67 |
| 17 | 88.38 | 23205 | 257.83 |
| 18 | 88.69 | 24570 | 273.00 |
| 19 | 88.98 | 25935 | 288.17 |
| 20 | 89.28 | 27300 | 303.33 |
| 21 | 89.50 | 28665 | 318.50 |
| 22 | 89.76 | 30030 | 333.67 |
| 23 | 90.01 | 31395 | 348.83 |
| 24 | 90.21 | 32760 | 364.00 |

[Table 8-2](#) gives the typical STC execution times for 24 intervals at different clock rates.

Table 8-2. Typical STC Execution Times

| Number of Intervals | @ HCLK = 180 MHz VCLK = 90 MHz STCCLK = 90 MHz | @ HCLK = 100 MHz VCLK = 100 MHz STCCLK = 50MHz | @ HCLK = 160 MHz VCLK = 80 MHz STCCLK = 80 MHz |
|---------------------|--|--|--|
| 24 | 364 μs | 655.20 μs | 409.50 μs |

8.4 STC Control Registers

STC control registers are accessed through Peripheral Bus (VBUSP) interface. Read and write access in 8, 16, and 32 bit are supported. The base address for the control registers is FFFF E600h.

NOTE: In suspend mode, all registers can be written irrespective of user or privilege mode.

Table 8-3. STC Control Registers

| Offset | Acronym | Register Description | Section |
|--------|---------------|--|--------------------------------|
| 00h | STCGCR0 | STC Global Control Register 0 | Section 8.4.1 |
| 04h | STCGCR1 | STC Global Control Register 1 | Section 8.4.2 |
| 08h | STCTPR | Self-Test Run Timeout Counter Preload Register | Section 8.4.3 |

8.4.1 STC Global Control Register 0 (STCGCR0)

This register is described in [Figure 8-3](#) and [Table 8-4](#).

Figure 8-3. STC Global Control Register 0 (STCGCR0) [offset = 00]

| | | | | | | | | | | | | | | | | | | |
|----------|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--------|----|---|
| 31 | | | | | | | | | | | | | | | | | 16 | |
| INTCOUNT | | | | | | | | | | | | | | | | | | |
| R/W-1 | | | | | | | | | | | | | | | | | | |
| 15 | | | | | | | | | | | | | | | | | 1 | 0 |
| Reserved | | | | | | | | | | | | | | | | RS_CNT | | |
| R-0 | | | | | | | | | | | | | | | | R/WP-0 | | |

LEGEND: R/W = Read/Write; R = Read only; WP = Write in privilege mode only; -n = value after reset

Table 8-4. STC Global Control Register 0 (STCGCR0) Field Descriptions

| Bit | Field | Value | Description |
|-------|----------|-------|---|
| 31-16 | INTCOUNT | | Number of intervals of self-test run This register specifies the number of intervals to run for the self-test run. This corresponds to the number of intervals to be ran from the value reflected in the current interval counter. |
| 15-1 | Reserved | 0 | Read returns 0. Writes have no effect. |
| 0 | RS_CNT | | Restart or Continue This bit specifies whether to continue the run from next interval onwards or to restart from interval 0. This bit gets reset after the completion of a self-test run. |
| | | 0 | Continue STC run from the previous interval. |
| | | 1 | Restart STC run from interval 0. |

NOTE: On a power-up reset or system reset, this register gets reset to its default values.

8.4.2 STC Global Control Register 1 (STCGCR1)

This register is described in [Figure 8-4](#) and [Table 8-5](#).

Figure 8-4. STC Global Control Register 1 (STCGCR1) [offset = 04h]

| | | | | | | | | | | | | | | | |
|-----|----------|--|--|--|--|--|--|--|--|--|---------|---|---|--|----|
| 31 | Reserved | | | | | | | | | | | | | | 16 |
| R-0 | | | | | | | | | | | | | | | |
| 15 | Reserved | | | | | | | | | | 4 | 3 | 0 | | |
| R-0 | | | | | | | | | | | STC_ENA | | | | |
| R-0 | | | | | | | | | | | R/WP-5h | | | | |

LEGEND: R/W = Read/Write; R = Read only; WP = Write in privilege mode only; -n = value after nPORST (power-on reset) or System reset

Table 8-5. STC Global Control Register 1 (STCGCR1) Field Descriptions

| Bit | Field | Value | Description |
|------|----------|------------|--|
| 31-4 | Reserved | 0 | Read returns 0. Writes have no effect. |
| 3-0 | STC_ENA | | Self-test run enable key |
| | | Ah | Self-test run enabled. |
| | | All Others | Self-test run disabled. |

NOTE: On a power-up reset or system reset, this register resets to its default values. Also, this register automatically resets to its default values at the completion of a self-test run.

8.4.3 Self-Test Run Timeout Counter Preload Register (STCTPR)

This register is described in [Figure 8-5](#) and [Table 8-6](#).

Figure 8-5. Self-Test Run Timeout Counter Preload Register (STCTPR) [offset = 08h]

LEGEND: R/W = Read/Write; R = Read only; WP = Write in privilege mode only; -n = value after nPORST (power-on reset) or System reset

Table 8-6. Self-Test Run Timeout Counter Preload Register (STCTPR)

| Bit | Field | Description |
|------|-------|--|
| 31-0 | RTOD | <p>Self-test timeout count preload</p> <p>This register contains the total number of VBUS clock cycles it will take before a self-test timeout error (TO_ERR) will be triggered after the initiation of the self-test run. This is a fail safe feature to prevent the device from hanging up due to a run away test during the self-test.</p> <p>The preload count value gets loaded into the self-test time out down counter whenever a self-test run is initiated (STC_KEY is enabled) and gets disabled on completion of a self-test run.</p> |

NOTE: On a power-up reset or system reset, this register gets reset to its default values.

8.4.4 STC Current ROM Address Register (STC_CADDR)

This register is described in [Figure 8-6](#) and [Table 8-7](#).

Figure 8-6. STC Current ROM Address Register (STC_CADDR) [offset = 0Ch]

LEGEND: R/W = Read/Write; R = Read only; -n = value after nPORST (power-on reset) or System reset

Table 8-7. STC Current ROM Address Register (STC_CADDR) Field Descriptions

| Bit | Field | Description |
|------|-------|---|
| 31-0 | ADDR | <p>Current ROM Address</p> <p>This register reflects the current ROM address (for micro code load) which is the current value of the STC program counter.</p> |

NOTE: When the RS_CNT bit in STCGCR0 is set to a 1 on the start of a self-test run, or on a power-up reset or system reset, this register resets to all zeroes.

8.4.5 STC Current Interval Count Register (STCCICR)

This register is described in [Figure 8-7](#) and [Table 8-8](#).

Figure 8-7. STC Current Interval Count Register (STCCICR) [offset = 10h]

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 8-8. STC Current Interval Count Register (STCCICR) Field Descriptions

| Bit | Field | Value | Description |
|-------|----------|-------|--|
| 31-16 | Reserved | 0 | Read returns 0. Writes have no effect. |
| 15-0 | N | | Interval Number This specifies the last executed interval number. |

NOTE: When the RS_CNT bit in STCGCR0 is set to a 1 or on a powerup reset, the current interval counter resets to the default value.

8.4.6 Self-Test Global Status Register (STCGSTAT)

This register is described in [Figure 8-8](#) and [Table 8-9](#).

Figure 8-8. Self-Test Global Status Register (STCGSTAT) [offset = 14h]

LEGEND: R/W = Read/Write; R = Read only; WP = Write in privilege mode only; -n = value after reset

Table 8-9. Self-Test Global Status Register (STCGSTAT) Field Descriptions

| Bit | Field | Value | Description |
|------|-----------|-------|---|
| 31-2 | Reserved | 0 | Read returns 0. Writes have no effect. |
| 1 | TEST_FAIL | 0 | Test Fail |
| | | 0 | Self-test run has not failed. |
| | | 1 | Self-test run has failed. |
| 0 | TEST_DONE | 0 | Test Done |
| | | 0 | Not completed. |
| | | 1 | Self-test run completed. |
| | | | The test done flag is set to a 1 for any of the following conditions: |
| | | | 1. When the STC run is complete without any failure |
| | | | 2. When a failure occurs on a STC run |
| | | | 3. When a timeout failure occurs |
| | | | Reset is generated to the CPU on which the STC run is being performed when TEST_DONE goes high (the test is completed). |

NOTE: The two status bits can be cleared to their default values on a write of 1 to the bits. Additionally when the `STC_ENA` key is written from a disabled state to enabled state, the two status flags get cleared to their default values. This register gets reset to its default value with power-on reset assertion.

8.4.7 Self-Test Fail Status Register (STCFSTAT)

This register is described in [Figure 8-9](#) and [Table 8-10](#).

Figure 8-9. Self-Test Fail Status Register (STCFSTAT) [offset = 18h]

| | | | | | | | | | | | | | | | | |
|----------|--|--|--|--|--|--|--|--|--|--|--------|---|-----------|---|-----------|--|
| 31 | | | | | | | | | | | | | 8 | | | |
| Reserved | | | | | | | | | | | | | | | | |
| R-0 | | | | | | | | | | | | | | | | |
| | | | | | | | | | | | 3 | 2 | 1 | 0 | | |
| Reserved | | | | | | | | | | | TO_ERR | | CPU2_FAIL | | CPU1_FAIL | |
| R-0 | | | | | | | | | | | R/WP-0 | | R/WP-0 | | R/WP-0 | |

LEGEND: R/W = Read/Write; R = Read only; WP = Write in privilege mode only; -n = value after nPORST (power-on reset) or System reset

Table 8-10. Self-Test Fail Status Register (STCFSTAT) Field Descriptions

| Bit | Field | Value | Description |
|------|-----------|-------|---|
| 31-3 | Reserved | 0 | Read returns 0. Writes have no effect. |
| 2 | TO_ERR | 0 | No time out error occurred. |
| | | 1 | Self-test run failed due to a timeout error. |
| 1 | CPU2_FAIL | 0 | CPU2 failure info No MISR mismatch for CPU2. |
| | | 1 | Self-test run failed due to MISR mismatch for CPU2. |
| 0 | CPU1_FAIL | 0 | CPU1 failure info No MISR mismatch for CPU1. |
| | | 1 | Self-test run failed due to MISR mismatch for CPU1. |

NOTE: The three status bits can be cleared to their default values on a write of 1 to the bits. Additionally when the STC_ENA key in STCGCR1 is written from a disabled state to an enabled state, the three status bits get cleared to their default values. This register gets reset to its default value with power-on reset assertion.

8.4.8 CPU1 Current MISR Register (CPU1_CURMISR[3:0])

This register is described in [Figure 8-10](#) through [Figure 8-13](#) and [Table 8-11](#).

Figure 8-10. CPU1 Current MISR Register (CPU1_CURMISR3) [offset = 1Ch]

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 8-12. CPU2 Current MISR Register (CPU2_CURMISR[3:0]) Field Descriptions

| Bit | Field | Description |
|-------|-------|--|
| 127-0 | MISR | MISR data from CPU2 This register contains the MISR data from the CPU2 for the most recent interval. This value is compared with the GOLDEN MISR value copied from ROM. |

NOTE: This register gets reset to its default value with power-on or system reset assertion.

8.4.10 STCSCSCR (Signature Compare Self-Check Register)

This register is described in [Figure 8-18](#). This register is used to enable the self-check feature of the CPU Self-Test Controller's (STC) signature compare logic. Self-check can only be done for the STC interval 0 by setting the RS_CNT bit in STCGCR0 to 1 to restart the self-test. The STC run will fail for signature miss-compare, provided the signature compare logic is operating correctly. To proceed with regular CPU self-test, STCSCSCR should be programmed to disable the self-check feature and clear the RS_CNT bit in STCGCR0 to 0. This register gets reset to its default value with any system reset assertion.

Figure 8-18. Signature Compare Self-Check Register (STCSCSCR) [offset = 3Ch]

LEGEND: R/W = Read/Write; R = Read only; WP = Write in privilege mode only; -n = value after nPORST (power-on reset) or System reset

Table 8-13. Signature Compare Self-Check Register (STCSCSCR) Field Descriptions

| Bit | Field | Value | Description |
|------|----------------|-----------------------|---|
| 31-5 | Reserved | | Reads return zeros, writes have no effect |
| 4 | FAULT_INS | 0 1 | Enable / Disable fault insertion. No fault is inserted Insert stuck-at-fault inside CPU so that STC signature compare will fail |
| 3-0 | SELF_CHECK_KEY | Ah Any other value | Signature compare logic self-check enable key Signature compare logic self-check is enabled. This allows a fault to be inserted using the FAULT_INS field. Signature compare logic self-check is disabled The FAULT_INS field has no effect in this case. |

8.5 STC Configuration Example

The following examples assume that the PLL is locked and selected as the system clock source with HCLK = 180 MHz and VCLK = 90 MHz.

8.5.1 Example 1: Self-Test Run for 24 Interval

This example explains the configurations for running STC Test for maximum Test Intervals 24.

1. Maximum STC clock rate support at 180 MHz HCLK is 90 MHz. Divide HCLK by 2 to achieve this clock rate. STCCLKDIV[26:24] register in the secondary system module frame at location 0xFFFF E108 is used.
STCCLKDIV[26:24] = 1
2. Clear CPU_RST status bit in the System Exception Status Register in the system module.
SYSESR[5] = 1
3. Configure the test interval count in STC module.
STCGCR0[31:16] = 24
4. Configure self-test run time out counter preload register.
STCTPR[31:0] = 0xFFFFFFFF
5. Enable CPU self-test.
STCGCR1[3:0] = 0xA
6. Perform a context save of CPU state and configuration registers that get reset on CPU reset.
7. Put the CPU in idle mode by executing the CPU idle instruction.
asm(" WFI")
8. Upon CPU reset, verify the CPU_RST status bit in the System Exception Status Register is set. This also verifies that no other resets occurred during the self-test.
SYSESR[5] == 1
9. Check the STCGSTAT register for the self-test status.
Check TEST_DONE bit before evaluating TEST_FAIL bit.
If TEST_DONE = 0 the self-test is not completed. restart the STC test by going to Step 5.
If (TEST_DONE = 1 and TEST_FAIL = 1) the self-test is completed and Failed.
 - Read STC Fail Status Register STCFSTAT[2:0] to identify the type of Failure (Timeout, CPU1 fail, CPU2 fail).
 In case there is no failure (TEST_DONE = 1 and TEST_FAIL = 0), the CPU self-test is completed successfully.
 - Recover the CPU status, configuration registers and continue the application software.

CPU Compare Module for Cortex-R4F (CCM-R4F)

This chapter describes the CPU compare module for Cortex-R4F (CCM-R4F). This device implements two instances of the Cortex-R4F CPU which are running in lock step to detect faults which may result in unsafe operating conditions. The CCM-R4F detects faults and signals them to an error signaling module (ESM).

NOTE: In general, R4F is used when referencing the Cortex CPU used in the Hercules family of devices; however, the floating-point functionality is a device-specific option and may not be included in some devices. Consult your device-specific datasheet to determine which core is included on your specific device being used.

| Topic | Page |
|--|------------|
| 9.1 Main Features | 377 |
| 9.2 Block Diagram..... | 377 |
| 9.3 Module Operation | 378 |
| 9.4 CCM-R4F Control Registers | 381 |

9.1 Main Features

Safety-critical applications require run-time detection of faults in the Central Processing Unit (CPU). For this purpose, the CPU Compare Module for Cortex-R4F (CCM-R4F) compares the core compare bus outputs of two Cortex-R4F CPUs running in a 1oo1D (one-out-of-one, with diagnostics) lockstep configuration. Any difference in the core compare bus outputs of the CPUs is flagged as an error. For diagnostic purposes, the CCM-R4F also incorporates a self-test capability to allow for boot time checking of hardware faults within the CCM-R4F itself.

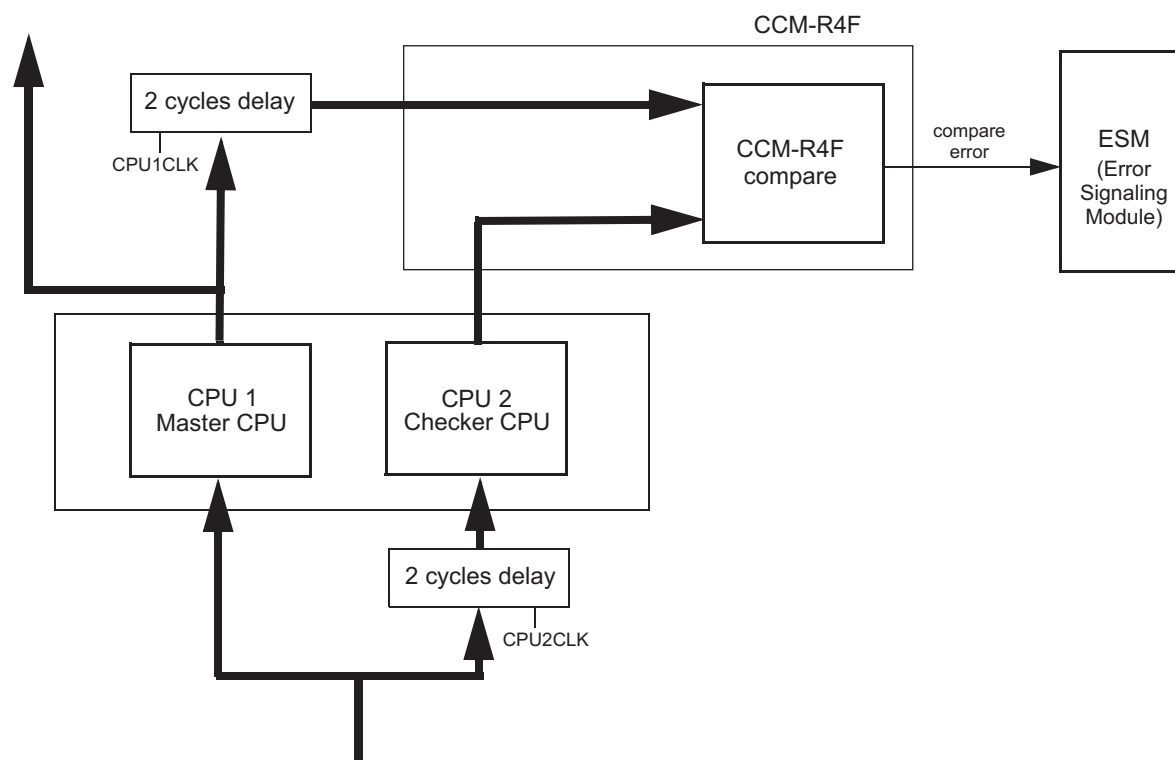

The main features of the CCM-R4F are:

- run-time detection of faults
- self-test capability
- error forcing capability

9.2 Block Diagram

Figure 9-1 shows the interconnection diagram of the CCM-R4F with the two Cortex-R4F CPUs. The core compare bus outputs of the CPUs are compared in the CCM-R4F. To avoid common mode impacts, the signals of the CPUs to be compared are temporally diverse. The output signals of the master CPU are delayed 2 cycles while the input signals of checker CPU are delayed 2 cycles.

Figure 9-1. Block Diagram

9.3 Module Operation

The CCM-R4F compares the core compare bus outputs of the master and checker Cortex-R4F CPUs on the microcontroller and signals an error on any mismatch. This comparison is started 6 CPU clock cycles after the CPU comes out of reset to ensure that CPU output signals have propagated to a known value after reset. Once comparison is started, the CCM module continues to monitor the outputs of two CPUs without any software intervention. Upon an error software needs to handle it.

The CCM-R4F can run in one of the following four operating modes:

1. 1001D lock step
2. self-test
3. error forcing
4. self-test error forcing

The operating mode can be selected by writing a dedicated key to the key register (MKEY).

9.3.1 1001D Lock Step Mode

This is the default mode on start-up.

In lock step mode, the compare bus output signals of both CPUs are compared. A difference in the CPU compare bus outputs is indicated by signaling an error to the ESM which sets the error flag “CCM-R4F - compare”.

NOTE: The CPU compare error asserts “CCM-R4F self-test error” flag as well. By doing this, the CPU compare error has two paths (“CCM-R4F - compare” and “CCM-R4F self-test error” flag) to the ESM, so that even if one of the paths fails, the error is still propagated to the ESM.

Not all internal registers of the Cortex-R4F CPU have fixed values upon reset. To avoid an erroneous CCMR4F compare error, the application software needs to ensure that the CPU registers of both CPUs are initialized with the same values before the registers are used, including function calls where the register values are pushed onto the stack.

9.3.2 Self-Test Mode

In self-test mode, the CCM-R4F checks itself for faults. During self-test, the compare error module output signal is deactivated. Any fault detected inside the CCM-R4F will be flagged by ESM error “CCM-R4F - self-test”.

In self-test mode, the CCM-R4F automatically generates test patterns to look for any hardware faults. If a fault is detected, then a self-test error flag is set, a self-test error signal is asserted and sent to the ESM, and the self-test is terminated immediately. If no fault is found during self-test, the self-test complete flag is set. In both cases, the CCM-R4F remains in self-test mode after the test has been terminated or completed, and the application needs to switch the CCM-R4F mode by writing another key to the mode key register (MKEY). During the self-test operation, the compare error signal output to the ESM is inactive irrespective of the compare result.

There are two types of patterns generated by CCM-R4F during self-test mode:

- (i) Compare Match Test
- (ii) Compare Mismatch Test

CCM-R4F first generates Compare Match Test patterns, followed by Compare Mismatch Test patterns. Each test pattern is applied on both CPU signal inputs of the CCM-R4F's compare block and clocked for one cycle. The duration of self-test is 3615 CPU clock cycles (GCLK).

NOTE: During self-test, both CPUs can execute normally, but the compare logic will not be checking any CPU signals. Also during self-test, only the compare unit logic is tested and not the memory mapped register controls for the CCM-R4F. The self-test is not interruptible.

9.3.2.1 Compare Match Test

During the Compare Match Test, there are four different test patterns generated to stimulate the CCM-R4F. An identical vector is applied to both input ports at the same time expecting a compare match. These patterns cause the self-test logic to exercise every CPU compare bus output signal in parallel. If the compare unit produces a compare mismatch then the self-test error flag is set, the self-test error signal is generated, and the Compare Match Test is terminated.

The four test patterns used for the Compare Match Test are:

- All 1s on both CPU signal ports
- All 0s on both CPU signal ports
- 0xAs on both CPU signal ports
- 0x5s on both CPU signal ports

These four test patterns will take four clock cycles to complete. illustrates the sequence of Compare Match Test.

Table 9-1. Compare Match Test Sequence

| CPU 1 Signal Position | | | | | | | | | CPU 2 Signal Position | | | | | | | | | Cycle |
|-----------------------|---|---|---|---|---|---|---|---|-----------------------|---|---|---|---|---|---|---|---|-------|
| n:8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 | n:8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 | |
| 1s | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1s | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 0 |
| 0s | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0s | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 1 |
| 0xA | 1 | 0 | 1 | 0 | 1 | 0 | 1 | 0 | 0xA | 1 | 0 | 1 | 0 | 1 | 0 | 1 | 0 | 2 |
| 0x5 | 0 | 1 | 0 | 1 | 0 | 1 | 0 | 1 | 0x5 | 0 | 1 | 0 | 1 | 0 | 1 | 0 | 1 | 3 |

9.3.2.2 Compare Mismatch Test

During the Compare Mismatch Test, the number of test patterns is equal to twice the number of CPU output signals to compare in lock step mode. An all 1s vector is applied to the CCM-R4F's CPU1 input port and the same pattern is also applied to the CCM-R4F's CPU2 input port but with one bit flipped starting from signal position 0. The un-equal vector will cause the CCM-R4F to expect a compare mismatch at signal position 0, if the CCM-R4F logic is working correctly. If, however, the CCM-R4F logic reports a compare match, the self-test error flag is set, the self-test error signal is asserted, and the Compare Mismatch Test is terminated.

This Compare Mismatch Test algorithm repeats in a domino fashion with the next signal position flipped while forcing all other signals to logic level 1. This sequence is repeated until every single signal position is verified on both CPU signal ports.

The Compare Mismatch Test is terminated if the CCM-R4F reports a compare match versus the expected compare mismatch. This test ensures that the compare unit is able to detect a mismatch on every CPU signal being compared. [Table 9-2](#) illustrates the sequence of Compare Mismatch Test. There is no error signal is sent to ESM if the expected errors are seen with each pattern.

Table 9-2. Compare Mismatch Test Sequence

| CPU 1 Signal Position | | | | | | | | | | CPU 2 Signal Position | | | | | | | | | | | | Cycle | |
|-----------------------|-------|----|---|---|---|---|---|---|---|-----------------------|---|-------|----|---|---|---|---|---|---|---|---|-------|---|
| n | n-1:8 | | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 | n | n-1:8 | | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 | | |

9.3.3 Error Forcing Mode

In error forcing mode, a test pattern is applied to the CPU related inputs of the CCM-R4F compare logic to force an error in the compare error output signal of the compare unit. The ESM error flag “CCM-R4F - compare” is expected after the error forcing mode completes. As a side effect, the “CCM-R4F self-test error” flag is also asserted whenever the CPU compare error is asserted.

Error forcing mode is similar to the Compare Mismatch Test operation of self-test mode in which an unequal vector is applied to the CCM-R4F CPU signal ports. The error forcing mode forces the compare mismatch to actually assert the compare error output signal. This ensures that faults in the path between CCM-R4F and ESM is detected.

Only one hardcoded test pattern is applied into CCM-R4F during error forcing mode. A repeated 0x5 pattern is applied to CPU1 signal port of CCM-R4F input while a repeated 0xA pattern is applied to the CPU2 signal port of CCM-R4F input. The error forcing mode takes one cycle to complete. Hence, the failing signature is presented for one clock cycle. After that, the mode is automatically switched to lock step mode. The key register (MKEY) will indicate the lock step key mode once it is switched to lock step mode. During the one cycle required by the error forcing test, the CPU output signals are not compared. User should expect the ESM to trigger a response (report the CCM-R4F fail). If no error is detected by ESM, then a hardware fault is present.

9.3.4 Self-Test Error Forcing Mode

In self-test error forcing mode, an error is forced at the self-test error signal. The compare unit is still running in lockstep mode and the key is switched to lockstep after one clock cycle. The ESM error flag “CCM-R4F - self-test” is expected after the self-test error forcing mode completes. Once the expected errors are seen, the application can clean the error through ESM module.

9.3.5 Operation During CPU Debug Mode

Certain debug operations place the CPU in a halting debug state where the code execution is halted. Because halting debug events are asynchronous, there is a possibility for the debug requests to cause loss of lockstep. CCM-R4F will disable upon detection of halting debug requests. Core compare error will not be generated and flags will not update. A CPU reset is needed to ensure the CPUs are again in lockstep and will also re-enable the CCM-R4F.

9.4 CCM-R4F Control Registers

[Table 9-3](#) lists the CCM-R4F registers. Each register begins on a 32-bit word boundary. The registers support 32-bit, 16-bit and 8-bit accesses. The base address for the control registers is FFFF F600h.

Table 9-3. CCM-R4F Control Registers

| Offset | Acronym | Register Description | Section |

10.1 Introduction

This chapter provides an overview of the oscillator and PLL clock source paths for the device.

The oscillator macro will pass a signal driven into the OSCIN pin to clock source 0 that is the device default clock source on reset. When a crystal or resonator with appropriate load circuitry is connected to OSCIN and OSCOUT, the oscillator macro drives the crystal/resonator to generate the input waveform. In addition to being directly usable as clock source 0, the oscillator clock is the input to the PLL.

The oscillator frequency is continuously monitored by a dedicated clock detect circuit. If the frequency falls out of a fixed range, the clock detect switches the clock from the oscillator to an internally generated, free-running frequency (generated by the low-power oscillator (LPO)).

The phase lock loop (PLL), a circuit in the microcontroller, is used to multiply the input frequency to some higher (device operation) frequency. This frequency synthesis is useful for generating higher frequencies than can be conveniently achieved with an external crystal or resonator. Additionally, the PLL allows the flexibility to be able to synthesize one of multiple frequency options from a given crystal or resonator.

Frequency modulation can be superimposed on the synthesized frequency. The modulation provides a means to reduce the impact of electromagnetic radiation from the device; this reduction in measured radiation can be useful in sensitive applications.

10.1.1 Features

The main features of the source clock path are:

- The oscillator may drive a crystal/resonator or be driven from an external source
- The clock detect provides continuous monitoring of the oscillator frequency and provides an automatic switch over to a free-running clock in case of oscillator failure.
- The FM-PLL module can be operated in either modulation or non-modulation mode.
- The phase-frequency detector assures lock to the fundamental reference frequency.

- $$f_{PLL} = \frac{f_{OSCIN}}{NR} \times \frac{NF}{OD \times R}$$
 (2)
 - Configurable prescale divider (NR) for the input clock
 - Configurable multiplier (NF)
 - Configurable postscale dividers (OD, R)
- The PLL may be used with modulation enabled.
 - Configurable modulation frequency (NS)
 - Configurable modulation depth (NV)
- The slip control circuitry provides flexible response to a PLL failure (slip) including reset or automatic switch over to oscillator.

10.2 Quick Start

The purpose of this section is to provide an overview of how to configure the oscillator and PLL clock paths on power-up. More detailed descriptions are presented in later sections. [Figure 10-1](#) shows the oscillator and PLL clock paths.

Figure 10-1. Clock Path From Oscillator Through PLL To Device

While power-on reset is asserted (low), the oscillator and low power oscillator (LPO) are enabled and start-up by default. After power-on reset is released to a high level, the clock detect circuit (CLKDET) begins to monitor the oscillator. If the oscillator is within a valid range, the oscillator becomes the default clock for the device as it exits reset; if the oscillator is not within a valid range, the clock detect selects the high-frequency low power oscillator as the default clock for the device.

The low power oscillator has a wide frequency range which also creates a large valid window for the clock detect; in order to refine the clock detect window, the low power oscillator can be trimmed. The initial trim value is stored in one-time programmable section of the flash memory, address 0xF008_01B4. Bits 31:16 of this word contain a 16 bit value that may be programmed into LPOMONCTL(15:0) in order to initialize the trim for both HF LPO and LF LPO. Software should read the initial trim values from flash and write them to the control register.

The PLL is disabled by default on power-up. The PLL control registers (PLLCTL1 and PLLCTL2) must be configured to set the desired output frequency. Then, the system PLL may be enabled (CSDISCLR.1). Similarly, the second PLL must be configured in PLLCTL3 and enabled (CSDISCLR.6). Each PLL has a valid bit that indicates the PLL is locked (CLKSRnV bit in the Clock Source Valid Status Register (CSVSTAT) of the System and Peripheral Control Registers).

Prior to selecting the PLL clock as the source for a clock domain (for example, GCLK, HCLK, ACLKV1), the domain and modules on the domain must be configured to accept the new frequency. An example of a module that should be configured prior to selecting the PLL as clock source for GCLK and HCLK is the memory wrapper to insure that access times are maintained correctly.

10.3 Oscillator

The clock generation path through the PLL begins with the oscillator. The oscillator consists of three separate pads -- OSCIN, OSCOUT, and Kelvin_GND (see Figure 10-2).

Figure 10-2. Clock Generation Path

The oscillator is responsible for two independent functions:

1. The oscillator is responsible for generating positive feedback in the external crystal/resonator with appropriate load and tank circuitry. At start-up, the oscillator amplifies random noise. The external circuitry acts like a band-pass and selects the crystal/resonator frequency to provide as positive feedback into the amplifier. The positive feedback increases the amplitude of the output waveform into the crystal/resonator (and the load circuitry), and the voltage waveform shows an envelope of increasing amplitude. The oscillator can drive a crystal frequency that is within the data sheet range $t_{c(OSC)}$.

Looking at the input waveform into OSCIN, the voltage waveform is an AC-coupled, filtered version of the OSCOUT waveform. The band-pass functionality of the crystal/resonator removes distortion from the OSCOUT waveform, leaving a sinusoidal input waveform.

NOTE: Vendor Validation of Resonators/Crystals

The crystal is a very tight bandpass filter while a resonator is a somewhat wider bandpass. The load circuitry pulls the center frequency of the bandpass.

Texas Instruments strongly encourages each customer to submit samples of the device to the resonator/crystal vendor for validation. The vendor is equipped to determine what load capacitances will best tune their resonator/crystal to the microcontroller device for optimum start-up and operation over temperature and voltage extremes. The vendor also factors in margins for variations in the microcontroller process.

2. The oscillator is also responsible for squaring-up the input waveform. This squaring-up converts the sinusoid into a square wave at the core logic levels. The input path limits the input frequency range as a low-pass filter with a cutoff frequency.

The oscillator has a frequency range that is determined by the driving capability of external crystals/resonators (feedback path). If a clock is driven directly into the oscillator, then the feedback path is not relevant and the frequency range is determined solely by the forward path (which typically allows a higher frequency); the device can support inputs within the data sheet range $t_{c(OSC_Sq)}$.

10.3.1 Oscillator Implementation

The oscillator operates at 3.3V and uses a constant current source to drive current onto the OSCOUT node. An internal transistor shunts the current (and current from the external circuitry) to GND. This current steering drives the voltage waveform on OSCOUT.

Figure 10-3. Oscillator Implementation

10.3.2 Oscillator Enable

The oscillator is enabled asynchronously when nPORRST is low.

The oscillator is enabled by clearing bit 0 in the Clock Source Disable Register (CSDIS) or setting bit 0 in the Clock Source Disable Clear Register (CSDISCLR) of the System and Peripheral Control Registers. The bit sends a start signal to the oscillator. Bit 0 of CSDIS is cleared to 0 by default on a system or power-on reset so that the oscillator starts-up by default. After the oscillator swings at a high-enough amplitude to pass an input clock into the core domain and nPORRST is released, 1024 oscillator periods are counted before setting the CLKSR0V bit in the Clock Source Valid Status Register (CSVSTAT) of the System and Peripheral Control Registers. The oscillator generates clock source 0 in the global clock module (GCM).

10.3.3 Oscillator Disable

The clock sources (for example, OSC, PLL) are disabled by setting the appropriate bit in the Clock Source Disable Register (CSDIS) or setting the appropriate bit in the Clock Source Disable Set Register (CSDISSET) of the System and Peripheral Control Registers. These bits *allow* the clock source to disable but do not force the behavior until the clock is no longer used as the source for a clock domain (for example, GCLK, VCLK, VCLK2, RTICLK). The CLKSR0V bit in the Clock Source Valid Status Register (CSVSTAT), of the System and Peripheral Control Registers, is cleared after clock disable is asserted (which occurs after all clock domains are stopped).

The oscillator disable signal places the oscillator into a low power state, disconnects the feedback (bias) resistor between OSCIN and OSCOUT, and OSCIN is grounded.

10.4 Low-Power Oscillator and Clock Detect (LPOCLKDET)

The Low-Power Oscillator (LPO) is comprised of two oscillators -- HF LPO and LF LPO -- in a single macro. The low-power oscillator and clock detect (LPOCLKDET) uses a relaxation oscillator to generate an internal clock whose frequency is NOT tightly controlled. This frequency is used to monitor the oscillator input frequency and is also available as an independent clock source in the GCM.

The LPO produces two frequencies:

- High-frequency low-power oscillator (HF LPO) with a nominal frequency of 9.6MHz and a range from 5.5MHz to 19.5MHz; the HF LPO generates clock source 5 in the GCM.
- Low-frequency low-power oscillator (LF LPO) with a nominal frequency of 85kHz; the LF LPO generates clock source 4 in the GCM.

A single current source drives current onto a capacitor; when the voltage on the capacitor exceeds some threshold, the clock toggles. The LPO uses a single current source and the two different comparators to generate the HF LPO and LF LPO frequencies. The LPO is controlled by 4 different bit fields -- CSDIS.(5:4), HFTRIM(4:0), LFTRIM(4:0), and BIASEN.

- CSDIS.5 enables/disables the comparator that generates HF LPO.
- CSDIS.4 enables/disables the comparator that generates LF LPO.
- The HF TRIM and LF TRIM bit fields vary the current into the comparator to independently trim the HF LPO and LF LPO frequencies.
- BIAS ENABLE (LPOMONCTL.24) enables/disables the current source that drives the LPO.

10.4.1 Clock Detect

The LPO HF clock frequency is typically near 9.6MHz but ranges from 5.5MHz to 19.5MHz. The clock detect establishes a window for the oscillator by:

| | |
|-------------------------------------|-----------------------------------|
| $OSCIN > HF\ LPO_{min} / 4$ | $OSCIN / 4 < HF\ LPO_{max}$ |
| $OSCIN > 5.5[MHz] / 4 = 1.375[MHz]$ | $OSCIN < 4 \times 19.5 = 78[MHz]$ |

The clock detect circuit works by checking for a rising edge on one clock (oscillator or HF LPO) between rising edges of the other clock. The result is that in addition to flagging incorrect, repeating frequencies, the circuit also fails due to transient conditions.

The low end of the clock detect window ignores a transient low phase of at least 12 HF LPO cycles.

NOTE: Clock Detection of Oscillator MUST be Disabled Before Disabling HF LPO

The HF LPO frequency is the comparison frequency for the oscillator. The clock detection must be disabled prior to disabling the HF LPO frequency.

If the clock detection is NOT disabled prior to disabling the HF LPO, the clock detect circuitry will fail the oscillator as too fast (compared to the non-existent HF LPO). The clock detect circuitry will switch to the non-existent clock, leaving the device without a valid clock.

10.4.2 Behavior on Oscillator Failure

If the oscillator frequency fails, the clock detects supplies:

- the HF LPO clock to GCM clock source 0 instead of the oscillator
- the HF LPO clock to GCM clock source 1 instead of the PLL

The HF LPO signal will be available as three different clock sources:

- GCM clock source 0 (replacing the oscillator)
- GCM clock source 1 (replacing the PLL)
- GCM clock source 5 as HF LPO

The automatic switch-over from oscillator to HF LPO allows the application to execute at a reduced frequency and respond to a problem with the external crystal/resonator. During and after an oscillator failure, the oscillator CLKSRnV bit in the Clock Source Valid Status Register (CSVSTAT), of the System and Peripheral Control Registers, is set along with the OSCFAIL flag in the Global Status Register (GLBSTAT), of the System and Peripheral Control Registers.

It is useful to explicitly change the GHVSRG register, defining the current clock source for GCLK/HCLK/VCLK domains, to the HF LPO after an oscillator failure.

When reset on oscillator failure is set, PLLCTL1.23 (ROF), the device responds to an oscillator failure by generating a device reset.

10.4.3 Recovery from Oscillator Failure

If the oscillator fails, the clock detect switches the HF LPO frequency onto the oscillator source into the GCM. The OSCFAIL flag in the Global Status Register (GLBSTAT), of the System and Peripheral Control Registers, is also set.

The oscillator may be re-enabled (though if the failure was caused by a hard-fault, the re-enable will fail) through the following procedure:

1. Switch all clock domains from the oscillator to the HF LPO (for example, GHVSRG uses HF LPO, ACLKV uses HF LPO or VCLK, and so on).
2. If the PLL is used, disable the PLL by setting the appropriate bit in the Clock Source Disable Set Register (CSDISSET) of the System and Peripheral Control Registers.
3. Disable the oscillator by setting the appropriate bit in the Clock Source Disable Set Register (CSDISSET). This action resets the clock detect and allows the oscillator to propagate through GCM clock source 0.
4. Re-enable the oscillator by setting the appropriate bit in the Clock Source Disable Clear Register (CSDISCLR) of the System and Peripheral Control Registers.
5. Clear the OSCFAIL flag in the Global Status Register (GLBSTAT) by writing a 1 to the bit. The PLL slip bits may also be set on an oscillator failure. These can also be cleared.
6. Switch the clock domains back to the oscillator.
7. Re-enable the PLL by setting the appropriate bit in the Clock Source Disable Clear Register (CSDISCLR).

NOTE: Clock Re-Enable Procedure Will Fail If Caused by a Hard Failure

Although it is possible to re-enable the oscillator after a failure, if the oscillator failure was caused by a hard fault (for example, disconnected crystal/resonator terminal), the re-enable process will fail.

10.4.4 LPOCLKDET Enable

The LPO is enabled by default while nPORRST is low. During this time, the current source initializes, holding the relaxation oscillator in reset until initialized. After the current source releases the HF LPO and the LF LPO, these clock frequencies slew to their final frequencies; the final frequency may be achieved while nPORRST is active or after its release. After, nPORRST is released, the HF LPO Valid signal is set 32 HF LPO clock cycles later.

The clock detect is enabled once the oscillator and HF LPO are valid. Because an oscillator failure could occur from reset, the clock detect logic must provide an override path. If the HF LPO is valid and the oscillator is not valid, the clock detect circuitry will become active (overriding the oscillator invalid signal) after 16K LF LPO cycles (about 200ms).

10.4.5 LPOCLKDET Disable

10.4.5.1 Disable Clock Detect

It is possible to disable the clock detect circuitry. For protection, this clock detect disable employs a 2-bit key:

- RANGE DET ENA SSET (CLKTEST.24) must be set to 1
- RANGE DET CTRL (CLKTEST.25) must be cleared to 0

In this case, the LPO HF and LF clocks are still active but the clock detect circuitry is disabled. The clock detect unconditionally switches GCM_CLK_SRC(0) back to the oscillator so care should be taken to insure that the oscillator is good before disabling the clock detect circuitry.

10.4.5.2 Disable LPO HF and LF Clocks

The LPO may be disabled by holding the relaxation oscillator clocks (HF and LF) in reset. The clock detect must be disabled, and any clock domains using either HF or LF clocks must be switched to a different clock source. The LPO HF clock is reset by setting CSDIS.5; CSDISSET.5 is an easy way to set specific bits without disturbing the rest of the register. The HF LPO clock disables several HF LPO cycles after CSDIS is set.

Similarly, the LPO LF clock is reset by setting CSDIS.4, and in a similar way CSDISSET.4 can set the specific CSDIS register bit without using a read-modify-write construction. The LF LPO disables several LF LPO cycles after CSDIS is set.

Restarting the LPO clocks from this condition is fast and is known as a warm re-start. The CSDISCLR register allows the user to clear CSDIS bits without using a read-modify-write code-construct.

10.4.5.3 Disable LPO Current Bias

The LPO current source may be disabled after the clock detect is disabled and HF and LF clock sources are disabled. Turning off this current source places the LPOCLKDET into its lowest power configuration. The bias may be disabled by clearing the BIAS ENABLE bit (LPOMONCTL.24).

Restarting the LPO when the bias current has been disabled requires the current source to initialize first and is, therefore slower than a warm re-start; re-enabling the LPO from this condition is known as a warm re-start (similar to what happens during nPORRST active).

10.4.6 Trimming the HF LPO Oscillator

The HF LPO range varies considerably around 9.6MHz from device to device. In order to provide tighter monitoring of the crystal/resonator, it is useful to trim the oscillator. During device test, a trim value is written into the one-time programmable section of the flash memory (OTP), address 0xF008_01B4. Bits 31:16 of this OTP word contain a 16 bit value that may be programmed into LPOMONCTL(15:0) in order to initialize the trim for both HF LPO and LF LPO.

When trimming the HF LPO, it is recommended to step the trim value so as not to make a large change to any TRIM setting.

After the initial trim, further trimming may be done in LPOMONCTL, using the dual clock compare module (see [Chapter 11](#)) in order to determine the resultant frequency. This module allows for comparison of two clock frequencies. Once the HF LPO is determined to be in-range with the initial HFTRIM setting from the OTP, the crystal oscillator may be used as a reference against which the HF LPO and LF LPO may be further adjusted.

10.5 PLL

The following bit fields from PLLCTL1 and PLLCTL2 configure the PLL:

- REFCLKDIV[5:0]
- PLLMUL[15:0]
- ODPLL[2:0]
- PLLDIV[4:0]
- SPR_AMOUNT[8:0]
- SPREADINGRATE[8:0]
- FMENA

The PLL is responsible for synthesizing an output frequency from the input clock (from the oscillator); [Figure 10-4](#) shows a simple block diagram of the PLL. The FM-PLL divides the reference input for a lower frequency input into the PLL ($f_{\text{INTCLK}} = f_{\text{CLKIN}}/\text{NR}$). The PLL multiplies this internal frequency by NF to get the VCO output clock frequency ($f_{\text{Output CLK}} = f_{\text{INTCLK}} \times \text{NF}$). The PLL output is subsequently divided by two prescale values (OD and R). The value of OD is an integer from 1 to 8 and R is an integer from 1 to 32. This output clock, PLL CLK, sources GCM clock source 1. Valid frequencies are shown in [Table 10-1](#) while [Table 10-2](#) shows how that encoding is generated from the PLL bit fields.

[$f_{\text{(post_ODCLK)}}$ and $f_{\text{(HCLK)}}$ are data sheet parameters.]

Table 10-1. Valid Frequency Ranges for PLL

| | Frequency Limit |
|-------------------------|--------------------------------|
| f_{CLKIN} | $f_{\text{(OSC_Sqr)}}$ |
| f_{INTCLK} | 1MHz - $f_{\text{(OSC_Sqr)}}$ |
| $f_{\text{Output CLK}}$ | 150MHz - 550MHz |
| $f_{\text{post-ODCLK}}$ | $f_{\text{(post_ODCLK)}}$ |
| $f_{\text{PLL CLK}}$ | $f_{\text{(HCLK)}}$ |

Figure 10-4. Operation of the FM-PLL Module

Table 10-2. PLL Value Encoding

| | PLL | |
|-----------|---|-----|
| NR | $NR = REFCLKDIV[5...0] + 1$ | (3) |
| NF | Non-modulated: $NF = \frac{(PLLMUL[15...0] + 1 \ll 8)}{256}$ | (4) |
| | Modulated: $NF = \frac{(PLLMUL[15...0] + MULMOD[8...0] + 1 \ll 8)}{256}$ | (5) |
| NV | $NV = \frac{(SPR_AMOUNT[8...0] + 1)}{2048}$ | (6) |
| NS | $NS = SPRRATE[8...0] + 1$ | (7) |
| OD | $OD = ODPLL[2...0] + 1$ | (8) |

NOTE: ODPLL change should occur prior to enabling asynchronous clock domains

Since changing the ODPLL bit-field causes the PLL CLK to be gated, these changes to ODPLL should be completed before configuring a clock domain for an asynchronous clock source. Some clock domains (for example, RTICLK, VCLK2) require a frequency relationship to the VCLK.

$$f_{VCLK} \geq 3 \times \frac{f_{RTISRC}}{RTIDIV}$$

If the PLL is clocking VCLK and it is stopped for some cycles, then the frequency relationship is temporarily violated.

Many asynchronous domains require frequency relationships between VCLK and the asynchronous domain. Therefore, if the PLL clock is the source for GCLK, HCLK and VCLK, then the gating produces a short-term change in the PLL clock frequency (and hence also the VCLK frequency). As such, this frequency change could violate the requirements for an asynchronous clock domain.

10.5.1 Modulation

Optionally, the frequency can be modulated, that is, a controlled jitter is introduced onto the baseline frequency of the PLL. This modulation mechanism is not shown in Figure 10-4. When the PLL is used in the modulating mode, the programmable modulation block varies the PLL frequency from the baseline frequency ($f_{\text{baseline}} = (f_{\text{CLKIN}}/NR) \times NF/(OD \times R)$) to $f_{\text{baseline}} \times (1 - 2 \times \text{Depth})$ in a period defined by $1/f_s$; the modulation waveform is triangular and should be enabled after lock.

The modulation is digital and the spreading profile is triangular, down-spread which implies:

- the modulation waveform is composed of a series of frequency steps.
- the modulation frequency and modulation depth are both well controlled due to their digital character.
- the average frequency during modulation is lower than the average frequency prior to enabling modulation. The depth of modulation, however, sets the new average frequency.
- the modulation frequency must be selected slower than the loop bandwidth. From a practical perspective, NS should be near 20.

The modulation fields have a simple geometric meaning:

- the modulation step size is:

$$\frac{NV}{NF} \times f_{\text{OutputCLK}} \quad (9)$$

- the number of steps per modulation period is $2 \times NS$
- the modulation depth is given by:

$$\Delta f = \frac{NS}{2} \times \frac{NV}{NF} \times f_{\text{OutputCLK}}$$

$$Depth [\%] = \frac{NS}{2} \times \frac{NV}{NF} \quad (10)$$

- the modulation frequency is:

$$T_{\text{mod}} = \frac{f_{\text{osc}}}{2 \times NR \times NS} \quad (11)$$

- MULMOD minimizes frequency offset when programmed as:

$$\frac{(SPR_AMOUNT[8..0] + 1)(SPRRATE[8..0] + 1)}{16} \quad (12)$$

NOTE: Modulation should be enabled after Lock

Enable modulation after the lock is completed.

10.5.2 PLL Output Control

The outputs from the PLL are the output clock, slip signals, and VALID.

- **RFSLIP** -- the RFSLIP signal indicates that the Output CLK is running *too fast* relative to INTCLK and sets a RFSLIP status flag in the Global Status Register (GLBSTAT), of the System and Peripheral Control Registers, if the slip signal is active during normal PLL operation; the RFSLIP flag is masked off while the PLL is not active and during the PLL's lock period.
- **FBSLIP** -- the FBSLIP signal indicates that the Output CLK is running *too slow* relative to INTCLK and sets a FBSLIP status flag in the Global Status Register (GLBSTAT), of the System and Peripheral Control Registers, if the slip signal is active during normal PLL operation; the FBSLIP flag is masked off while the PLL is not active and during the PLL's lock period.
- **PLL Slip** -- Logical-OR of the two PLL slip signals. Typically this signal is used to generate a consolidated slip signal to the device (for example, error logic or exception generation). Also used to gate VALID.

NOTE: Clearing Slip Bits

In order to clear any of the slip bits, it is necessary to disable the PLL first.

- **VALID** -- is driven based upon whether the output clock, PLL CLK, is gated or not. However, the VALID signal is dependent upon the PLL Slip signals so that VALID cannot be set if either slip signal is active.
- **PLL Clock** -- The PLL output clock runs at the programmed frequency. When enabled, it takes some time to acquire the programmed frequency (see [Section 10.5.2.1](#)). Similarly, the disable has some timing/constraints (see [Section 10.5.2.2](#)).

10.5.2.1 PLL Enable

After setting the PLL control registers, the clock source is enabled by clearing the appropriate bit in the Clock Source Disable Register (CSDIS) or setting the appropriate bit in the Clock Source Disable Clear Register (CSDISCLR) of the System and Peripheral Control Registers. The bit sends a signal to the PLL that starts the process of enabling the PLL.

1. The PLL checks to make sure that the oscillator is ON. If not, it turns the oscillator ON.
2. The PLL begins a locking process in which the PLL slews from a starting frequency point to the programmed frequency. During this lock period, the PLL slip signals are typically active, and the PLL masks off the signals during this phase. The lock phase takes the following length of time:

| Parameter | Value |
|--------------------------|---|
| Lock | $T_{\text{Lock}} = (512 \times T_{\text{OSCIN}}) + (1024 \times \text{NR} \times T_{\text{OSCIN}})$ |
| Enable clocks after lock | $T_{\text{Enable}} = 6 \times T_{\text{OSCIN}}$ |

3. After the lock phase is complete (when lock counters expire), the PLL releases the slip signals to the system.
4. Then, after the slip signals are released and a delay to enable the clocks, the clock is released to the system and the appropriate CLKSRnV bit for the PLL is set in the Clock Source Valid Status Register (CSVSTAT) of the System and Peripheral Control Registers.

10.5.2.2 PLL Disable

The clock sources (for example, OSC, PLL) are disabled by setting the appropriate bit in the Clock Source Disable Register (CSDIS) or setting the appropriate bit in the Clock Source Disable Set Register (CSDISSET) of the System and Peripheral Control Registers. These bits *allow* the clock to disable but do not force the behavior until the clock is no longer used as the source for a clock domain (for example, GCLK, VCLK, VCLK2, RTICLK).

The PLL receives a signal to disable after the clock is no longer used by any clock domain. Within the PLL, the clock is disabled and the appropriate CLKSRnV bit for the PLL in the Clock Source Valid Status Register (CSVSTAT), of the System and Peripheral Control Registers, becomes inactive. Then the PLL is placed into a low-power state after the following length of time: $T_{\text{Enable}} = 150 \times T_{\text{OSCIN}}$

10.5.2.3 OD-divider Change

The PLL gates the clock if the ODPLL bit-field is changed while the PLL is active. The output clock from the PLL is gated for 3 or 12 OSCIN clock cycles. As the post-ODCLK is gated in the low phase, the output clock to the device -- PLL CLK -- may be gated in a high or low phase though the transition is always glitchless: $T_{\text{ODPLL}} = 3 \times T_{\text{OSCIN}}$

NOTE: ODPLL change should occur prior to enabling asynchronous clock domains

Since changing the ODPLL bit-field causes the PLL CLK to be gated, these changes to ODPLL should be completed before configuring a clock domain for an asynchronous clock source. Some clock domains (for example, RTICLK, VCLK2) require a frequency relationship to the VCLK.

$$f_{\text{VCLK}} \geq 3 \times \frac{f_{\text{RTISRC}}}{\text{RTIDIV}}$$

If the PLL is clocking VCLK and it is stopped for some cycles, then the frequency relationship is temporarily violated.

Many asynchronous domains require frequency relationships between VCLK and the asynchronous domain. Therefore, if the PLL clock is the source for GCLK, HCLK and VCLK, then the gating produces a short-term change in the PLL clock frequency (and hence also the VCLK frequency). As such, this frequency change could violate the requirements for an asynchronous clock domain.

10.5.2.4 Changing the PLL Operating Point While the PLL is Active

Once the valid bit (CLKSRnV bit in the Clock Source Valid Status Register (CSVSTAT) of the System and Peripheral Control Registers) is set, software may change values to the PLL. If the change of values results in a small percentage change to the VCO frequency ($\Delta f_{\text{OutputCLK}} < 0.1 \times f_{\text{OutputCLK}}$), then these changes can be done on-the-fly. In this mode, the values are updated into the PLL synchronously, and the PLL re-locks to the new value without gating the clocks or the slip bits. If the operating point change is too large, then the slip bits will be set.

Conversely, if the changes to the VCO frequency are large, then the PLL should be disabled prior to changing the values. Typically, any change to the REFCLKDIV field or large changes to the PLLMUL field in the PLL Control Register 1 (PLLCTL1) of the System and Peripheral Control Registers requires a complete disable-and-relock strategy.

10.5.2.5 Summary of PLL Timings

In addition to controlling the lock period and disabling the clock during an ODPLL change, the PLL also generates reset delays. When power-on reset is released (nPORRST 0 --> 1), that release is delayed by 1024 OSCIN cycles so that it is released at the same time that the oscillator valid is asserted. The system reset release is delayed by an additional 8 oscillator clock cycles.

Table 10-3. Summary of PLL Timings

| Parameter | Value |
|---------------------------|---|
| nPORRST delay | $T_{nPORRST} = 1024 \times T_{OSCIN}$ |
| nRST delay | $T_{nRST} = 1032 \times T_{OSCIN}$ |
| OSC valid | $T_{OSCVALID} = 1024 \times T_{OSCIN}$ |
| Lock | $T_{Lock} = (512 \times T_{OSCIN}) + (1024 \times NR \times T_{OSCIN})$ |
| Enable clocks after lock | $T_{Enable} = 6 \times T_{OSCIN}$ |
| Disable clocks after lock | $T_{Enable} = 150 \times T_{OSCIN}$ |
| Change ODPLL | $T_{ODPLL} = 3 \times T_{OSCIN}$ |

10.5.3 Behavior on PLL Fail

The PLL allows flexible response to a PLL failure (slip). Like the oscillator, the PLL clock is configured by default to automatically switch-over to the oscillator in case of a PLL slip. (In this case, the oscillator sources GCM clock source 1 as well as GCM clock source 0. Also, if the oscillator fails, LPO HF is sourced to both GCM clock sources 0 and 1.)

The PLL slip outputs indicate that the PLL is running either too fast or too slow. These error output toggle when the PLL is locking and when the PLL is disabling. The PLL blocks these slip outputs during these times, leaving them active only while the PLL is active.

A slip after the PLL has locked and while it is active is an indication of a PLL failure. The PLL provides slip-filtering which enhances the flexibility of the PLL's response to failure. The slip-filtering circuit samples the slip based on HF LPO. The filter defines the number of consecutive HF LPO cycles for which the slip signal must be active before the slip is recognized. This slip is latched in the RFSLIP and FBSLIP status flags in the Global Status Register (GLBSTAT) of the System and Peripheral Control Registers.

The PLL may enable/disable the automatic switch over as well as the error signaling; if the error signaling is enabled, a PLL slip may be configured to generate a reset. The automatic switch-over and suppression of the error signals are controlled by the bypass on slip bit field -- BPOS[1:0] (PLLCTL1.(30:29)). When BPOS[1:0] is disabled (BPOS[1:0] = 10b):

- automatic response to the PLL slip is prevented
- ESM/exception is NOT generated
- reset on slip is not generated regardless of the state of the ROS bit
- status bits are set on a PLL slip independent of BPOS[1:0]

When BPOS[1:0] is enabled (BPOS[1:0] = 00b OR 01b OR 11b):

- PLL slip causes the clock source into GCM clock source 1 to shift from the PLL to the oscillator
- ESM/exception is generated
- reset on slip is generated if ROS is set

The effect of BPOS[1:0] on the system is shown in [Figure 10-5](#).

Figure 10-5. PLL Slip Detection and Reset/Bypass Block Diagram

10.5.4 Recovery from a PLL Failure

If PLL1 fails, the PLL's slip causes the valid flag to be locked and causes the clock source into GCM clock source 1 to shift from the PLL to the oscillator. The RFSLIP or FBSLIP status flags in the Global Status Register (GLBSTAT) of the System and Peripheral Control Registers are also set. PLL1 may be re-enabled (though if the failure was caused by a hard-fault, the re-enable will fail) through the following procedure:

1. Switch all clock domains from PLL1 to the oscillator (for example, GHVSRG uses oscillator, ACLKV uses oscillator or VCLK, and so on).
2. Disable PLL1 with CSDISSET. This action disables the PLL and causes the slip signal to no longer be driven. Valid is not released until the slip is cleared.
3. Clear the RFSLIP or FBSLIP status flags in the Global Status Register (GLBSTAT) of the System and Peripheral Control Registers by writing a 1 to the bit.
4. Re-enable PLL1 with CSDISCLR.
5. Switch the clock domains back to PLL1.

If PLL2 fails, the PLL's slip causes the valid flag to be locked. There is no autonomous change of clock source for PLL2. Neither the RFSLIP or FBSLIP status flags in the Global Status Register (GLBSTAT) of the System and Peripheral Control Registers are set. PLL2 may be re-enabled in a similar procedure to re-enabling PLL1 (though if the failure was caused by a hard-fault, the re-enable will fail):

1. Switch all clock domains from PLL2 to the oscillator (for example, GHVSRG uses oscillator, ACLKV uses oscillator or VCLK, and so on).
2. Disable PLL2 with CSDISSET. This action disables the PLL and causes the slip signal to no longer be driven. Valid is not released until the slip is cleared.
3. Reset PLL2 Valid by writing a 1 to both RFSLIP and FBSLIP status flags in the Global Status Register (GLBSTAT) of the System and Peripheral Control Registers (even though they are not set by the slip).
4. Re-enable PLL2 with CSDISCLR.
5. Switch the clock domains back to PLL2.

10.5.5 PLL Modulation Depth Measurement

The PLL contains a circuit for estimating the depth of the modulation. The circuit counts clock edges over a fixed window of the modulation waveform (SSW_CAPTURE_COUNT in SSWPLL2) and clock edges over the entire waveform (SSW_CLKOUT_COUNT in SSWPLL3). The capture ends after a pre-determined number of clock edges in SSW_CLKOUT_COUNTER as set in TAP_COUNTER_DIS. There are $2 \times NR$ windows per modulation waveform. The procedure for estimating the modulation depth is:

1. While GCLK is sourced by the oscillator and the PLL is enabled with modulation, configure SSWPLL1 as follows:
 - (a) CAPTURE_WINDOW_INDEX is set equal to NR.
 - (b) COUNTER_RESET is set.
 - (c) TAP_COUNTER_DIS is set to disable the measurement after SSW_CLKOUT_COUNT captures this number of clocks. The measurement is disabled after the set tap is set AND the modulation cycle ends.
 - (d) Ensure that EXT_COUNTER_EN is cleared.
2. Ensure that both SSW_CAPTURE_COUNT and SSW_CLKOUT_COUNT are cleared (by the COUNTER_RESET).
3. Set COUNTER_EN and clear COUNTER_RESET. This step releases the reset and enables the counter to begin counting.
4. After a wait loop, poll for COUNTER_READ_READY to set. After the bit is set, read SSW_CAPTURE_COUNT and SSW_CLKOUT_COUNT.
5. Compute the modulation depth as:

$$Depth = abs\left(1 - \frac{2 \times NR \times SSW_CAPTURE_COUNT}{SSW_CLKOUT_COUNT}\right) \quad (13)$$

10.5.6 PLL Frequency Measurement Circuit

The same circuit that is used to measure modulation depth is also available to measure the average frequency of the PLL. In this mode, the PLL output (before the R-divider) is captured in SSW_CLKOUT_COUNT while the oscillator is captured in SSW_CAPTURE_COUNT. The procedure for using the PLL frequency measurement circuit is:

1. While the PLL is enabled, set EXT_COUNTER_EN.
2. Set COUNTER_EN. This bit clears both SSW_CAPTURE_COUNT and SSW_CLKOUT_COUNT and then immediately enables for counting.
3. Wait for some software delay loop.
4. Clear COUNTER_EN. Wait for COUNTER_READ_READY to set. Read both SSW_CAPTURE_COUNT and SSW_CLKOUT_COUNT and compute the ratio of PLL multiplication as:

$$\frac{NF}{NR \times OD} = \frac{SSW_CLKOUT_COUNT}{SSW_CAPTURE_COUNT} \quad (14)$$

5. Note that CAPTURE_WINDOW_INDEX, COUNTER_RESET, TAP_COUNTER_DIS are not used in this procedure.

10.5.7 PLL2

PLL2 drives GCM clock source 6.

The PLL is identical to PLL1, except modulation is disabled on this instance of the PLL. Also, the PLL typically does not clock the system, there is no automatic switch over feature. Any PLL error can be handled by the CPU.

PLL2 is programmed through PLLCTL3.

10.6 PLL Control Registers

The clock module has two registers (PLLCTL1 and PLLCTL2) located within the System and Peripheral Control Registers, plus it has four bits located in other System and Peripheral Control Registers.

The FM-PLL is off at power-on. The clock source is enabled by clearing the appropriate bit in the Clock Source Disable Register (CSDIS) or setting the appropriate bit in the Clock Source Disable Clear Register (CSDISCLR) of the System and Peripheral Control Registers. [CSDISCLR and Clock Source Disable Set Register (CSDISSET) also enable/disable the PLL and oscillator (and other clock sources).]

The LPOCLKDET module generates the OSCFAIL flag in the Global Status Register (GLBSTAT), of the System and Peripheral Control Registers, if a problem with the reference oscillator is detected. The slip signals are also registered in the RFSLIP and FBSLIP status flags in the Global Status Register (GLBSTAT), of the System and Peripheral Control Registers, in order to indicate the source of a clock failure.

The appropriate CLKSRnV bit for the PLL is set in the Clock Source Valid Status Register (CSVSTAT) of the System and Peripheral Control Registers.

The following sections describe the PLL registers used in the system module. These registers support 8, 16, and 32-bit write accesses. The reset values for these registers are configured so that an input frequency in the range from 5MHz to 20MHz generates a valid clock.

Table 10-4. PLL Module Registers

| Offset | Acronym | Register Description | Section |
|------------|----------|---|----------------------------------|
| FFFF FF30h | CSDIS | Clock Source Disable Register | Section 2.5.1.10 |
| FFFF FF34h | CSDISSET | Clock Source Disable Set Register | Section 2.5.1.11 |

10.6.1 PLL Modulation Depth Measurement Control Register (SSWPLL1)

Figure 10-6 illustrates this register and Table 10-6 provides the bit descriptions. This register applies to PLL1, but does not apply to PLL2.

Figure 10-6. SSW PLL BIST Control Register 1 (SSWPLL1) [offset = FF24h]

| | | | | | | | | | | | | | | | | | |
|----------|----------------------|---------------|------------|-----------------|---|---|----------------|--|--|--|--|--|--|--|--|--|----|
| 31 | Reserved | | | | | | | | | | | | | | | | 16 |
| R-0 | | | | | | | | | | | | | | | | | |
| 15 | CAPTURE_WINDOW_INDEX | | | | | | | | | | | | | | | | 8 |
| R/W-0 | | | | | | | | | | | | | | | | | |
| 7 | 6 | 5 | 4 | 3 | 1 | 0 | | | | | | | | | | | |
| Reserved | COUNTER_READ_READY | COUNTER_RESET | COUNTER_EN | TAP_COUNTER_DIS | | | EXT_COUNTER_EN | | | | | | | | | | |
| R-0 | R-0 | R/W-1 | R/W-0 | R/W-0 | | | R/W-0 | | | | | | | | | | |

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 10-6. SSW PLL BIST Control Register 1 (SSWPLL1) Field Descriptions

| Bit | Field | Value | Description |
|-------|----------------------|--------|---|
| 31-16 | Reserved | 0 | Read returns 0. Writes have no effect. |
| 15-8 | CAPTURE_WINDOW_INDEX | 0-FFh | The capture counter present in the PLL wrapper will count the PLL clock edges when the current modulation phase capture window value is equal to these bits. Should be set equal to NR. |
| 7 | Reserved | 0 | Read returns 0. Writes have no effect. |
| 6 | COUNTER_READ_READY | 0 1 | Counter read ready. Indicates that SSW_CAPTURE_COUNT (SSWPLL2) and SSW_CLKOUT_COUNT (SSWPLL3) can be read. 0 Counter registers in SSWPLL2 and SSWPLL3 are not ready to read. 1 Counter registers in SSWPLL2 and SSWPLL3 are ready to read. |
| 5 | COUNTER_RESET | 0 1 | Counter reset. If EXT_COUNTER_EN = 0, COUNTER_RESET resets SSW_CAPTURE_COUNT (SSWPLL2) and SSW_CLKOUT_COUNT (SSWPLL3). If EXT_COUNTER_EN = 1, this bit is ignored. 0 No impact to counters 1 If the EXT_COUNTER_EN bit is 0, then counters SSW_CAPTURE_COUNT and SSW_CLKOUT_COUNT will be held in the reset state. If EXT_COUNTER_EN bit is 1, then this bit will be ignored by the PLL wrapper. |
| 4 | COUNTER_EN | 0 1 | Counter enable. If EXT_COUNTER_EN = 0, COUNTER_EN initializes the modulation depth measurement. (In this mode, the disable is set to occur automatically.) If EXT_COUNTER_EN = 1, the counters are enabled/disabled with COUNTER_EN. 0 If EXT_COUNTER_EN = 0, COUNTER_EN = 0 indicates that the counters are inactive. If EXT_COUNTER_EN = 1, COUNTER_EN = 0 disables the counters. 1 If EXT_COUNTER_EN = 0, COUNTER_EN = 1 indicates that the counters are still active. If EXT_COUNTER_EN = 1, COUNTER_EN = 1 enables the counters. |

Table 10-6. SSW PLL BIST Control Register 1 (SSWPLL1) Field Descriptions (continued)

| Bit | Field | Value | Description |
|-----|-----------------|-------|---|
| 3-1 | TAP_COUNTER_DIS | | The value in this register is used to program a particular bit in CLKOUT counter. When that particular bit in CLKOUT counter becomes 1, then both the CLKOUT counter and the CAPTURE counter will stop counting when EXT_COUNTER_EN = 0. When EXT_COUNTER_EN = 1, this bit field is not used. |
| | | 0 | Bit 16 of CLKOUT counter is selected. When this bit is set and the modulation period finishes, the counters are disabled and READ_READY_FLAG is set. |
| | | 1h | Bit 18 of CLKOUT counter is selected. |
| | | 2h | Bit 20 of CLKOUT counter is selected. |
| | | 3h | Bit 22 of CLKOUT counter is selected. |
| | | 4h | Bit 24 of CLKOUT counter is selected. |
| | | 5h | Bit 26 of CLKOUT counter is selected. |
| | | 6h | Bit 28 of CLKOUT counter is selected. |
| | | 7h | Bit 30 of CLKOUT counter is selected. |
| 0 | EXT_COUNTER_EN | 0 | Modulation Depth Measurement mode |
| | | 1 | Frequency Measurement mode |

10.6.2 SSW PLL BIST Control Register 2 (SSWPLL2)

This is an observation register used to log counter value for the capture counter inside the PLL wrapper. This register applies to PLL1, but does not apply to PLL2. The SSWPLL2 register is shown in [Figure 10-7](#) and described in [Table 10-7](#).

Figure 10-7. SSW PLL BIST Control Register 2 (SSWPLL2) [offset = FF28h]

LEGEND: R = Read only; -n = value after reset

Table 10-7. SSW PLL BIST Control Register 2 (SSWPLL2) Field Descriptions

| Bit | Field | Value | Description |
|------|-------------------|--------------|---|
| 31-0 | SSW_CAPTURE_COUNT | 0-FFFF FFFFh | Capture count. This register returns the value of the capture count. When EXT_COUNTER_EN = 0, this counter increments within a fixed modulation window. When EXT_COUNTER_EN = 1, this counter increments based upon the oscillator. |

10.6.3 SSW PLL BIST Control Register 3 (SSWPLL3)

This is observation register used to log counter value for CLKOUT counter inside PLL wrapper. This register applies to PLL1, but does not apply to PLL2. The SSWPLL3 register is shown in [Figure 10-8](#) and described in [Table 10-8](#).

Figure 10-8. SSW PLL BIST Control Register 3 (SSWPLL3) [offset = FF2Ch]

LEGEND: R = Read only; -n = value after reset

Table 10-8. SSW PLL BIST Control Register 3 (SSWPLL3) Field Descriptions

| Bit | Field | Value | Description |
|------|-------------------|--------------|---|
| 31-0 | SSW_CAPTURE_COUNT | 0-FFFF FFFFh | Value of CLKout count register. This counter increments based upon the PLL output (prior to the R-divider). |

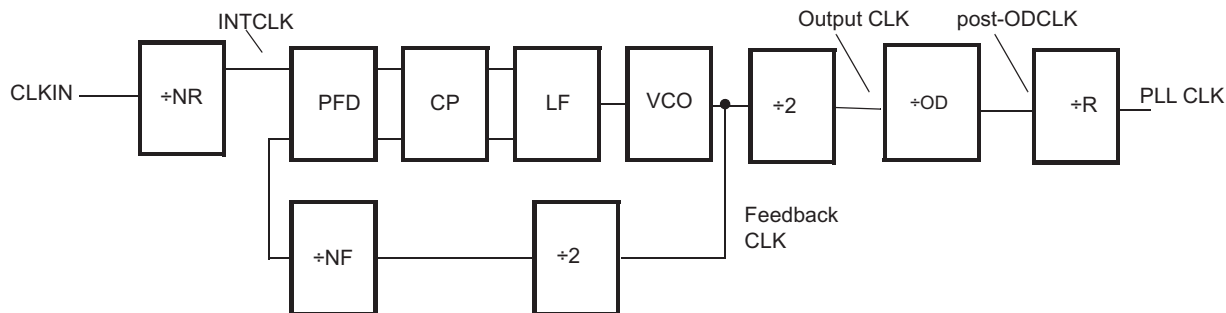

10.7 Phase-Locked Loop Theory of Operation

The PLL block consists of six logical sub-blocks:

- Phase-Frequency Detector (PFD)
- Charge Pump (CP)
- Loop Filter (LF)
- Voltage-Controlled Oscillator (VCO)
- Frequency Modulation
- Slip Detector

Figure 10-9 illustrates the sub-blocks in a basic PLL circuit. The VCO adjusts its frequency until the two signals into the PFD have the same phase and frequency. The feedback path (from VCO to PFD) divides the frequency of the feedback signal by $2 \times NF$; this feedback divider requires the VCO to generate a frequency $2 \times NF$ times greater than the internal frequency ($OSCIN/NR$). In the forward path (from VCO to PLL CLK), the $/2$ block creates a clean duty cycle.

Figure 10-9. Basic PLL Circuit

10.7.1 Phase-Frequency Detector

The phase-frequency detector (PFD) compares the input reference phase/frequency to the phase/frequency of the feedback divider and generates two signals: an *up* pulse and a *down* pulse that drive a charge pump. The resulting charge, when integrated by the circuit at the LF pin, provides a VCO control voltage, as shown in Figure 10-10.

Figure 10-10. PFD Timing

The width of the up pulse and the down pulse depends on the difference in phase between the two inputs. For example, when the reference input leads the feedback input by 10 ns, then an up pulse of approximately 10 ns is generated (see [Figure 10-10](#)). On the other hand, when the reference input lags the feedback input by 10 ns, then a down pulse of approximately 10 ns is generated. When the two inputs are exactly in phase, the up pulse and down pulse become essentially zero-width. These pulses are fed to the charge pump block, which meters charge into the low-pass loop filter.

The advantage of a phase-frequency detector over a phase-only detector is that it cannot lock to a harmonic or subharmonic of the reference. This important property also ensures that the output frequency of the VCO is always exactly $2 \times N_F$ times the reference frequency.

The reference feedback frequency is based upon the VCO frequency and the feedback divider. Fractional multiplication is achieved by changing the feedback divider real-time in order to create the fractional multiplication. As an example, if a multiplier of 100.5 is selected, the feedback divider divides by 100 and 101 in equal proportions; in this case, the PLLMUL bit field would be programmed as 99.5 (0x6380). This fractional multiplication is useful when trying to achieve final frequencies that are non-integer to the input frequency (for example, a final frequency that is a prime number). The fractional portion of the divider should be small compared to the multiplier and so it is recommended that the fractional portion relate to parts in 16, implying that the last 4 bits should always be 0.

10.7.2 Charge Pump and Loop Filter

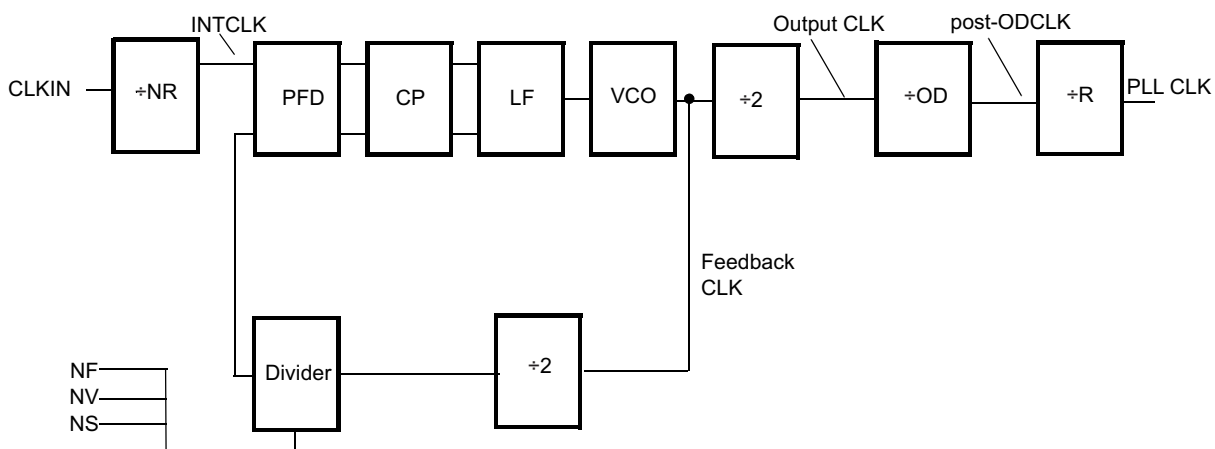

The charge pump (CP) add or remove charge from the loop filter based on the pulses coming from the phase-frequency detector (PFD).

Two components of the filter output signal are summed together: an integral component and a proportional component. The integral component maintains a DC level going to the VCO to set its frequency, and the proportional component makes the VCO track changes in phase to minimize jitter. The capacitors and resistors required for the filter are integrated in silicon.

10.7.3 Voltage-Controlled Oscillator

The output frequency of the VCO is proportional to its input control voltage, which is generated by the charge pump via the integrated loop filter. If the VCO oscillates too slowly, the feedback phase begins to lag the reference phase at the PFD, which increases the control voltage at the VCO. Conversely, if the VCO oscillates too fast, the feedback phase begins to lead the reference phase at the PFD, which decreases the control voltage at the VCO. These two actions keep the VCO running at the correct frequency multiple of the reference.

Figure 10-11. PLL Modulation Block Diagram

10.7.4 Frequency Modulation

The output clock of the PLL changes frequency in a controlled way, centered around the unmodulated output frequency. The modulation block directly modulates the VCO frequency at the loop filter, and creates the triangular frequency modulation (see Figure 10-12).

Figure 10-12. Frequency vs. Time

10.8 Programming Example

This section provides an example of how to program the PLL. For non-modulation settings, the PLLCTL1 and PLLCTL2 settings from 130nm process devices can be used without modification.

Suppose that, using a 20MHz crystal, the application requires:

- 180MHz GCLK (and HCLK) frequency
- 100 kHz spreading frequency
- 0.5% spreading depth

1. Choose an NR and NS such that:

$$\bullet \quad \frac{f_{CLKIN}}{NR \times f_s} \geq 40 \quad (15)$$

$$\bullet \quad f_s \equiv \frac{f_{CLKIN}}{2 \times NR \times NS} \quad (16)$$

$$\bullet \quad 2 \times NS = \frac{f_{CLKIN}}{NR \times f_s} \geq 40 \quad (17)$$

- (NR,NS) = {(5,20), (4,25), (2,50), (1,100)}
- Either NR = 5 and NS = 20 or NR = 4 and NS = 25 are reasonable. Another choice (NR, NS) = (3, 33) is possible if the modulation frequency can vary from 100KHz.

2. Choose Output CLK frequency as integer divider of output frequency near to 330MHz. Output CLK frequency shall not exceed 550MHz or fall below 150MHz.

The integer values for 180MHz are 360MHz or 540MHz. 360MHz is close to the target frequency of 330MHz and we use this frequency.

3. In this case, either of the below equations are suitable choices for getting to 360MHz. Choose NR = 5, NS = 20 and set NF = 90.

$$\frac{f_{CLKIN}}{NR} = \frac{20[MHz]}{4} = 5[MHz] \quad \text{or} \quad \frac{f_{CLKIN}}{NR} = \frac{20[MHz]}{5} = 4[MHz] \quad (18)$$

4. Select the output divider OD so that the post-ODCLK frequency does not exceed the maximum frequency of output divider R (device specific frequency). In this case, choose OD = 2 and R = 1.
5. Compute the divider value NV:

$$Depth = \frac{0.5}{100} = \frac{NV}{NF} \times \frac{NS}{2} = \frac{NV}{90} \times \frac{20}{2} \quad (19)$$

$$NV = 0.045$$

6. If it is important to maintain the same average frequency in modulation as in non-modulation, either NF should be modified OR program the MULMOD bit field. The modulation fields create a multiplier offset equal to:

$$\Delta NF = \frac{NV \times NS}{2} \quad (20)$$

If using MULMOD[8:0], then:

$$\Delta NF = \frac{MULMOD[8...0]}{256} = \frac{NV \times NS}{2} = \frac{0.045 \times 20}{2} \quad (21)$$

$$MULMOD[8...0] = \frac{0.045 \times 20}{2} \times 256 = 115.2 \quad (22)$$

MULMOD will be set to 115.

7. Convert the PLL parameters into bit field values:
 - NR = 5, implies that REFCLKDIV[5:0] = 4
 - NS = 20, implies that SPRATE[8:0] = 19 = 0x13
 - NF = 90, implies that PLLMUL[15:0] = 0x5900
 - OD = 2, implies that ODPLL[2:0] = 1
 - R = 1, implies that PLLDIV[4:0] = 0
 - NV = 0.045, implies that SPR_AMOUNT[8:0] = 91 = 0x5B
 - MULMOD[8:0] = 115 = 0x73
8. Setting only these fields (that is, not BPOS, ROF, or ROS) yields:

PLLCTL1 = 0x00045900

PLLCTL2 = 0x04C7325B

When FM ENA is turned on, PLLCTL2 = 0x84C7325B

The Output CLK is centered in the range from 150MHz to 550MHz at 360MHz.

NF = 90 falls within the multiplier range from 1 to 256.

OD is selected so that post-ODCLK meets the device specification.

Dual-Clock Comparator (DCC) Module

This chapter describes the dual-clock comparator (DCC) module.

| Topic | Page |
|--|-------------|
| 11.1 Introduction | 410 |
| 11.2 Module Operation | 411 |
| 11.3 Clock Source Selection for Counter0 and Counter1 | 415 |
| 11.4 DCC Control Registers | 416 |

11.1 Introduction

The primary purpose of a DCC module is to measure the frequency of a clock signal using a second known clock signal as a reference. This capability can be used to ensure the correct frequency range for several different device clock sources, thereby enhancing the system safety metrics.

11.1.1 Main Features

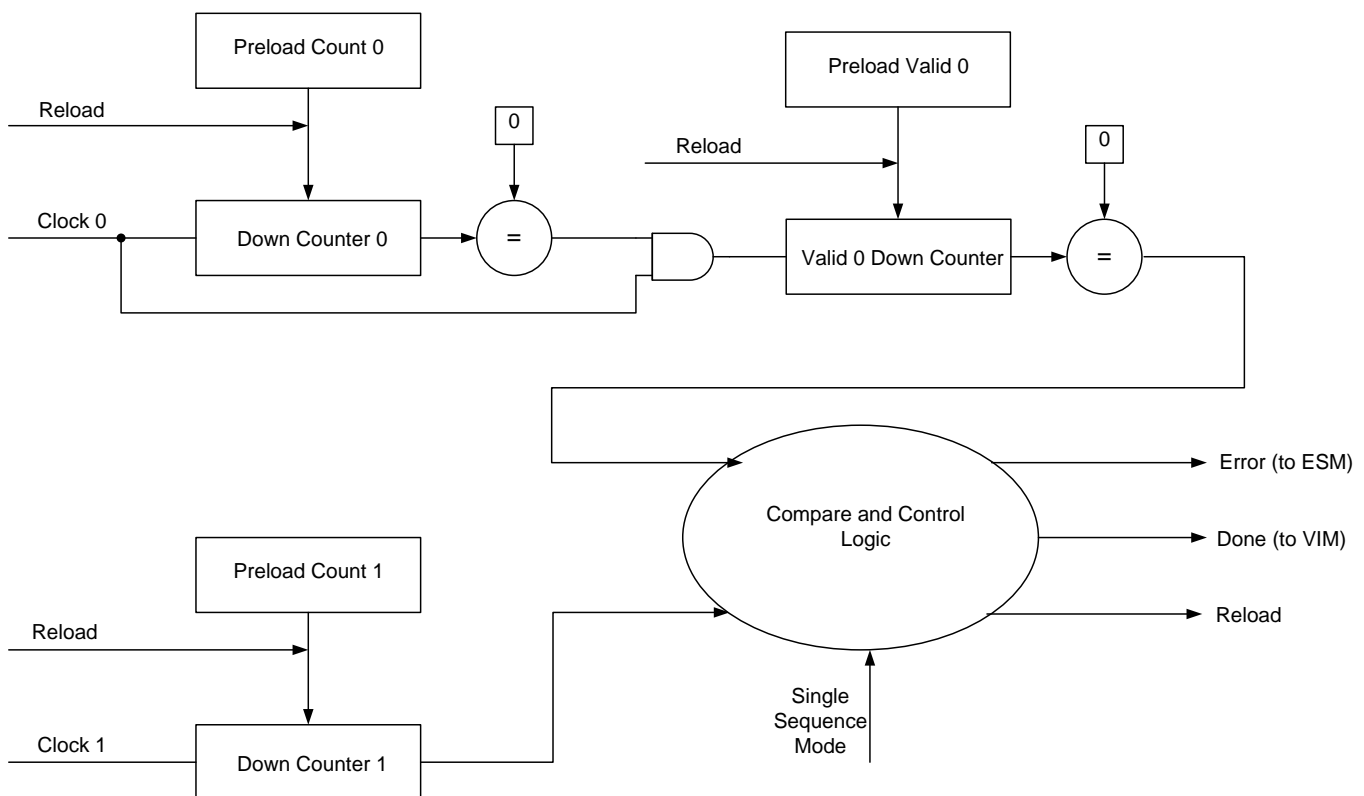

The main features of each of the DCC modules are:

- Allows application to ensure that a fixed ratio is maintained between frequencies of two clock signals
- Supports the definition of a programmable tolerance window in terms of number of reference clock cycles
- Supports continuous monitoring without requiring application intervention
- Also supports a single-sequence mode for spot measurements
- Allows selection of clock source for each of the counters resulting in several specific use cases

11.1.2 Block Diagram

Figure 11-1 illustrates the main concept of the DCC module.

Figure 11-1. DCC Operation

11.2 Module Operation

As shown in [Figure 11-1](#), the DCC contains two counters – counter0 and counter1, which are driven by two signals – clock0 and clock1. The application programs the seed values for both these counters. The application also configures the tolerance window time by configuring the valid counter for clock0.

Counter0 and counter1 both start counting simultaneously once the DCC is enabled. When counter0 counts down to zero, this automatically triggers the count down of the tolerance window counter (valid0).

The DCC module can be used in two different operating modes:

11.2.1 Continuous Monitoring Mode

In this mode, the DCC is used by the application to ensure that two clock signals maintain the correct frequency ratio. Suppose the application wants to ensure that the PLL output signal (clock source # 1) always maintains a fixed frequency relationship with the main oscillator (clock source # 0).

- In this case, the application can use the main oscillator as the clock0 signal (for counter0 and valid0) and the PLL output as the clock1 (for counter1).
- The seed values of counter0, valid0 and counter1 are selected such that if the actual frequencies of clock0 and clock1 are equal to their expected frequencies, then the counter1 will reach zero either at the same time as counter0 or during the count down of the valid0 counter.
- If the counter1 reaches zero during the count down of the valid0 counter, then all the counters (counter0, valid0, counter1) are reloaded with their initial seed values once valid0 has also counted down to zero.
- This sequence of counting down and checking then continues as long as there is no error, or until the DCC module is disabled.
- The counters also all get reloaded if the application resets and restarts the DCC module.

Error Conditions:

An error condition is generated by any one of the following:

1. Counter1 counts down to 0 before Counter0 reaches 0. This means that clock1 is faster than expected, or clock0 is slower than expected. It includes the case when clock0 is stuck at 1 or 0.
2. Counter1 does not reach 0 even when Counter0 and Valid0 have both reached 0. This means that clock1 is slower than expected. It includes the case when clock1 is stuck at 1 or 0.

Any error freezes the counters from counting. An application may then read out the counter values to help determine what caused the error.

11.2.1.1 Error Conditions

While operating in continuous mode, the counters get reloaded with the seed values and continue counting down under the following conditions:

- The module is reset or restarted by the application, OR
- Counter0, Valid 0 and Counter1 all reach 0 without any error

Figure 11-2. Counter Relationship

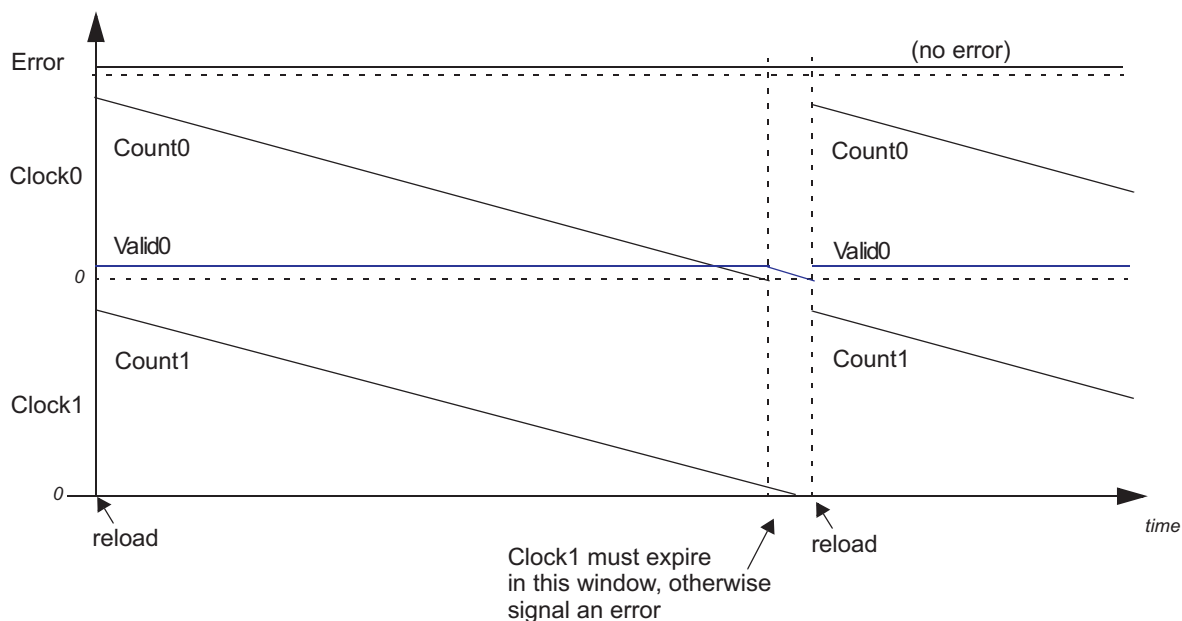

Figure 11-3. Clock1 Slower Than Clock0 - Results in an Error and Stops Counting

Figure 11-4. Clock1 Faster Than Clock0 - Results in an Error and Stops Counting

Figure 11-5. Clock1 Not Present - Results in an Error and Stops Counting

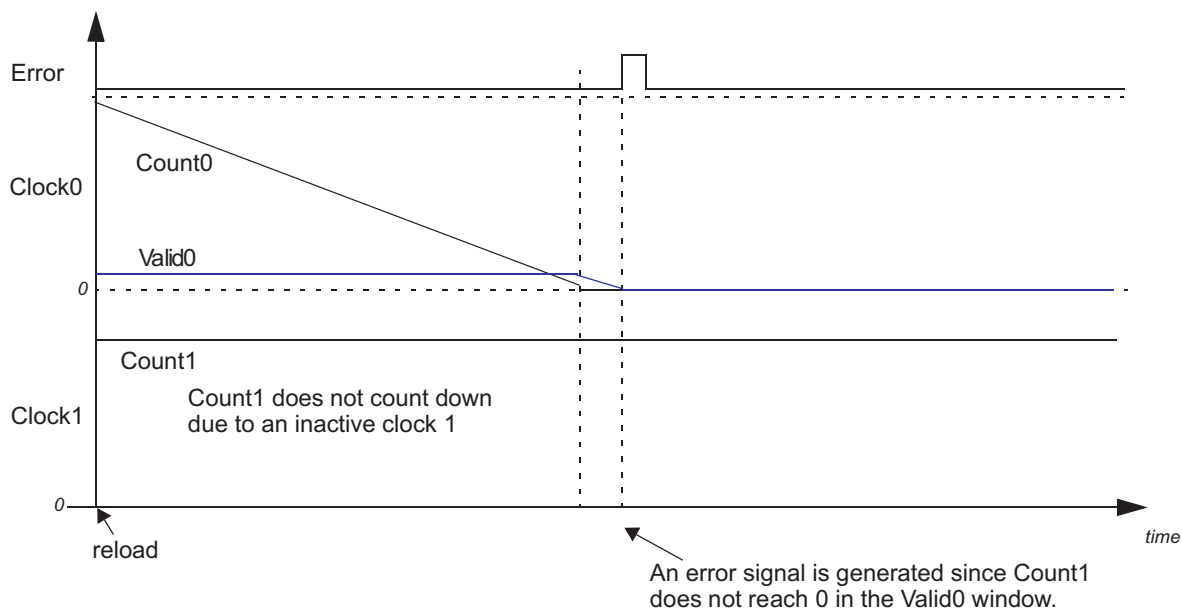

Figure 11-6. Clock0 Not Present - Results in an Error and Stops Counting

11.2.2 Single-Shot Measurement Mode

The DCC module can be programmed to count down one time by enabling the single-shot mode. In this mode, the DCC stops operating when the down counter0 and the valid counter0 reach 0. Alternatively, the DCC can be programmed to stop counting when the down counter1 reaches 0.

At the end of one sequence of counting down in this single-shot mode, the DCC gets disabled automatically, which prevents further counting. This mode is typically used for spot measurements of the frequency of a signal. This frequency could be an unknown for the application before the measurement.

Example Usage of Single-Shot Measurement Mode: Trimming the High-Frequency Low-Power Oscillator

A practical example of the usage of the spot measurement mode is in trimming the HF LPO (clock source # 5) using the main oscillator as a reference. This measurement sequence would proceed as follows:

- The application sets up the seed values for counter0 and valid0 for the duration of the measurement. Suppose the main oscillator frequency is 10MHz and the intended duration of the measurement is 500μs. The application needs to configure a seed value of 5000.
- These 5000 counts need to be divided between the counter0 and the valid0 counters. The minimum value for the valid0 seed is 4, so the application can configure counter0 seed value as 4996 and the valid0 seed value as 4.
- Suppose the HF LPO frequency is truly unknown. In this case the application can choose the maximum allowed seed value for counter1. This increases the probability of counter0 and valid0 counting down while the counter1 has still not fully counted down to zero. The maximum allowed seed value for counter1 is 1048575.
- Once the DCC is enabled, the counters counter0 and counter1 both start counting down from their seed values.
- When counter0 reaches zero, it automatically triggers the valid0 counter.
- When valid0 reaches zero, if counter1 is not zero as well, an ERROR status flag is set and a "DCC error" is sent to the ESM. Counter1 is also frozen so that it stops counting down any further. The application can enable an interrupt to be generated from the ESM whenever this DCC error is indicated. Refer the device datasheet to identify the ESM group and channel where the DCC error is connected.

- The DCC error interrupt service routine can then check the value of counter1 when the error was generated. Suppose that the counter1 now reads 1044575. This means that counter1 has counted 1048575 - 1044575, or 4000 cycles within the 500µs measurement period. This means that the average frequency of the HF LPO over this 500µs period was 4000 cycles / 500µs, or 8MHz.
- The application then needs to clear the ERROR status flag and restart the DCC module so that it is ready for the next spot measurement.

If there is no error generated at the end of the sequence, then the DONE status flag is set and a DONE interrupt is generated. The application must clear the DONE flag before restarting the DCC.

The conditions that cause a DCC error are identical between the continuous monitoring mode and the single-shot measurement mode.

Error Conditions:

An error condition is generated by any one of the following:

1. Counter1 counts down to 0 before Counter0 reaches 0. This means that clock1 is faster than expected, or clock0 is slower than expected. It includes the case when clock0 is stuck at 1 or 0.
2. Counter1 does not reach 0 even when Counter0 and Valid0 have both reached 0. This means that clock1 is slower than expected. It includes the case when clock1 is stuck at 1 or 0.

Any error freezes the counters from counting. An application may then read out the counter values to help determine what caused the error.

Freezing Counters when Counter1 Reaches Zero:

The DCC module also allows the counters to be frozen when the counter1 reaches zero. This allows one of the clock sources for counter1 to be used as a reference for measuring one of the clock sources for counter0. The error conditions are the same as those where (counter0=0 and valid0=0) define the condition when the DCC counters are frozen. That is, an error is indicated if counter0 and valid0 become zero while counter1 is still non-zero. In this case, however, the application would typically set up the seed values such that the counter1 will become zero before counter0. Essentially the measurement period is defined by the seed value of the counter1. Note that this is also an error condition, and the interrupt service routine can use the measurement period and the actual cycles counted by counter1 to determine the frequency of the clock0 signal.

11.3 Clock Source Selection for Counter0 and Counter1

Refer the device datasheet to identify the available options for selecting the clock sources for both counters of the DCC module. Some microcontrollers may include multiple instances of the DCC module. This will also be identified in the device datasheet.

The selection of the clock sources for counter0 and counter1 is done by a combination of the KEY, CNT0 CLKSRC and CNT1 CLKSRC control fields of the CNT0CLKSRC and CNT1CLKSRC registers.

11.4 DCC Control Registers

This section describes the dual-clock comparator (DCC) module control and status registers. The registers support 8-bit, 16-bit or 32-bit writes and are aligned on a word (32-bit) boundary. [Table 11-1](#) shows address offsets from the module base address. The base address for the control registers is FFFF EC00h for DCC1 and FFFF F400h for DCC2.

Table 11-1. DCC Control Registers

When an error occurs, the counters stop and this field is set to 5h automatically disabling the DCC counter in hardware.</p> <p>Read: Counters are enabled.</p> <p>Write: Load counters with their seed values and begin counting. It is recommended to write Ah to enable counters to protect against single-bit errors.</p> |

11.4.2 DCC Revision Id Register (DCCREV)

Figure 11-8 and Table 11-3 describe the DCC Revision Id register.

Figure 11-8. DCC Revision Id Register (DCCREV) [offset = 4h]

LEGEND: R = Read only; -n = value after reset

Table 11-3. DCC Revision Id Register (DCCREV) Field Descriptions

| Bit | Field | Value | Description |
|-------|----------|-------|---|
| 31-30 | SCHEME | 01 | Reads return 01, writes have no effect. |
| 29-28 | Reserved | 0 | Read returns 0. Writes have no effect. |
| 27-16 | FUNC | 0 | Functional release number. Reads return 0x000, writes have no effect. |
| 15-11 | RTL | 0 | Design release number. Reads return 0x00, writes have no effect. |
| 10-8 | MAJOR | 2h | Major revision number. Reads return 0x2, writes have no effect. |
| 7-6 | CUSTOM | 0 | Custom version number. Reads return 0x0, writes have no effect. |
| 5-0 | MINOR | 4h | Minor revision number. Reads return 0x4, writes have no effect. |

11.4.3 DCC Counter0 Seed Register (DCCNT0SEED)

Figure 11-9 and Table 11-4 describe the DCC Counter0 Seed register.

Figure 11-9. DCC Counter0 Seed Register (DCCNT0SEED) [offset = 8h]

LEGEND: R/W = Read/Write; R = Read only; WP = Write in privileged mode only; -n = value after reset

Table 11-4. DCC Counter0 Seed Register (DCCNT0SEED) Field Descriptions

| Bit | Field | Value | Description |
|-------|-------------|-------|--|
| 31-20 | Reserved | 0 | Read returns 0. Writes have no effect. |
| 19-0 | COUNT0 SEED | | Seed value for DCC Counter0. Read in any operating mode returns the current value of Counter0. Writing in privileged mode only sets the current seed value for Counter0. |

NOTE: Seed for Counter0 must be non-zero

The DCC must only be enabled after programming a non-zero value in the COUNT0 SEED register.

11.4.4 DCC Valid0 Seed Register (DCCVALID0SEED)

Figure 11-10 and Table 11-5 describe the DCC Valid0 Seed register.

Figure 11-10. DCC Valid0 Seed Register (DCCVALID0SEED) [offset = Ch]

| R/WP-0 | | |

LEGEND: R/W = Read/Write; R = Read only; WP = Write in privileged mode only; -n = value after reset

Table 11-5. DCC Valid0 Seed Register (DCCVALID0SEED) Field Descriptions

| Bit | Field | Value | Description |
|-------|-------------|-------|--|
| 31-16 | Reserved | 0 | Read returns 0. Writes have no effect. |
| 15-0 | VALID0 SEED | | Seed value for DCC Valid0. This value defines the window within which the Counter1 must reach 0. This window needs to be at least 4 cycles wide. Read in any operating mode returns the current value of seed for Valid0. Writing in privileged mode only sets the current seed value for Valid0. Writes in user mode are ignored. |

NOTE: Seed for Valid0 must be at least 0x4

The DCC must only be enabled after programming a value greater than or equal to 0x4 in the VALID0 SEED register.

11.4.5 DCC Counter1 Seed Register (DCCCNT1SEED)

Figure 11-11 and Table 11-6 describe the DCC Counter1 Seed register.

Error Signaling Module (ESM)

This chapter provides the details of the error signaling module (ESM) that aggregates device errors and provides the capability to define internal and external error response based on error severity.

| Topic | Page |
|---|-------------|
| 12.1 Overview | 425 |
| 12.2 Module Operation | 427 |
| 12.3 Recommended Programming Procedure | 431 |
| 12.4 Control Registers | 432 |

12.1 Overview

The Error Signaling Module (ESM) collects and reports the various error conditions on the microcontroller. The error condition is categorized based on a severity level. Error response is then generated based on the category of the error. Possible error responses include a low-priority interrupt, high-priority interrupt, and an external pin action.

12.1.1 Features

- Up to 128 error channels are supported, divided into 3 different groups:
 - 64 Group1 (low-severity) channels with configurable interrupt generation and configurable $\overline{\text{ERROR}}$ pin behavior
 - 32 Group2 (high-severity) channels with predefined interrupt generation and predefined $\overline{\text{ERROR}}$ pin behavior
 - 32 Group3 (high-severity) channels with no interrupt generation and predefined $\overline{\text{ERROR}}$ pin behavior. These channels have no interrupt response as they are reserved for CPU based diagnostics that generate aborts directly to the CPU.
- Dedicated device $\overline{\text{ERROR}}$ pin to signal an external observer
- Configurable timebase for $\overline{\text{ERROR}}$ pin output
- Error forcing capability for latent fault testing

12.1.2 Block Diagram

As shown in Figure 12-1, the ESM channels are divided into three groups. Group1 channels are considered to be low-severity. Group1 errors have a configurable interrupt response and configurable $\overline{\text{ERROR}}$ pin behavior. Note that the ESM Status Register 1 (ESMSR1) for error group1 gets updated, regardless of whether an ESM interrupt for that Group1 channel is enabled or not. Group2 channels are connected to higher-severity error signals. Group2 errors generate a non-maskable high-priority interrupt to the CPU and assert the $\overline{\text{ERROR}}$ pin. Group3 channels indicate errors of the highest severity. Most of these errors cause a CPU abort. Any group3 errors that do not cause a CPU abort must be checked and handled as part of the start-up sequence. Check the specific part's datasheet for identifying group3 errors and their expected responses. As most group3 errors cause a CPU abort, no additional interrupt request is required to be sent to the CPU. Group3 errors always assert the $\overline{\text{ERROR}}$ pin output.

The ESM interrupt and $\overline{\text{ERROR}}$ pin behavior are also summarized in Table 12-1.

Figure 12-1. Block Diagram

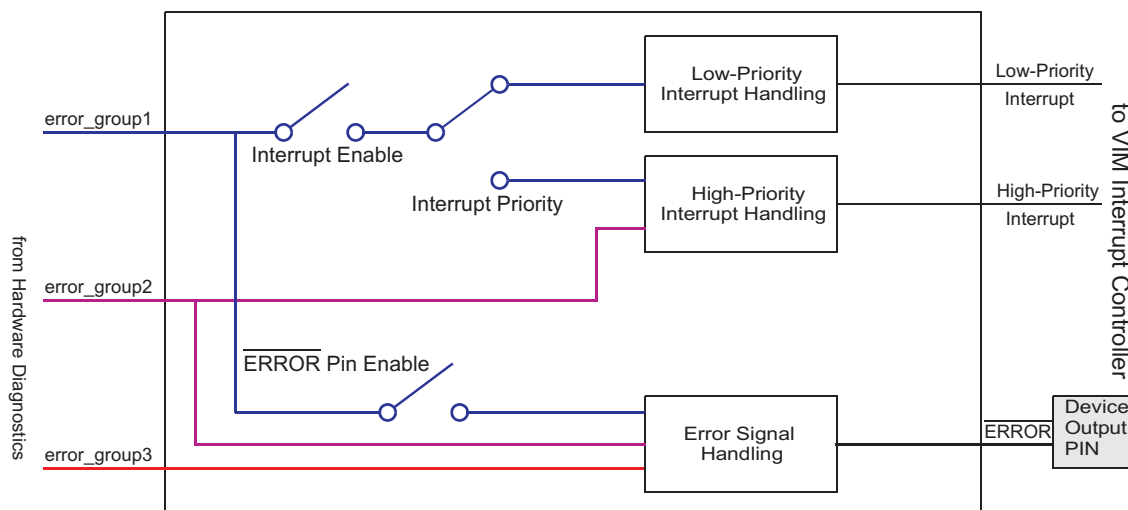

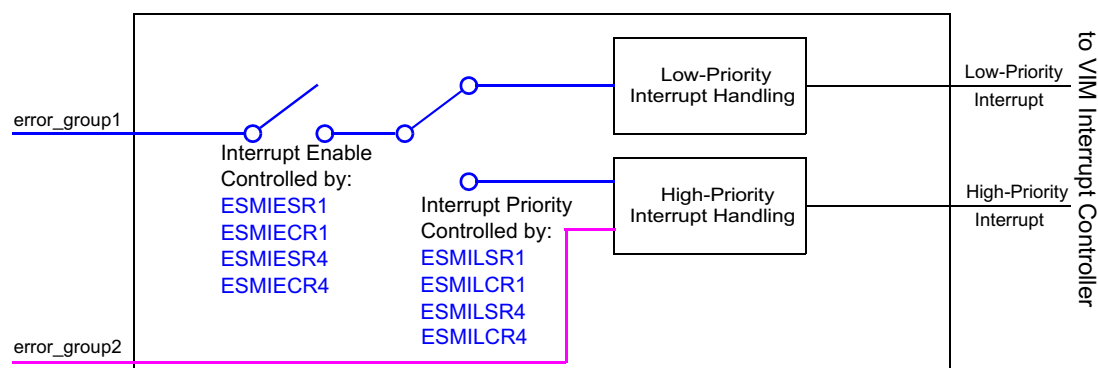

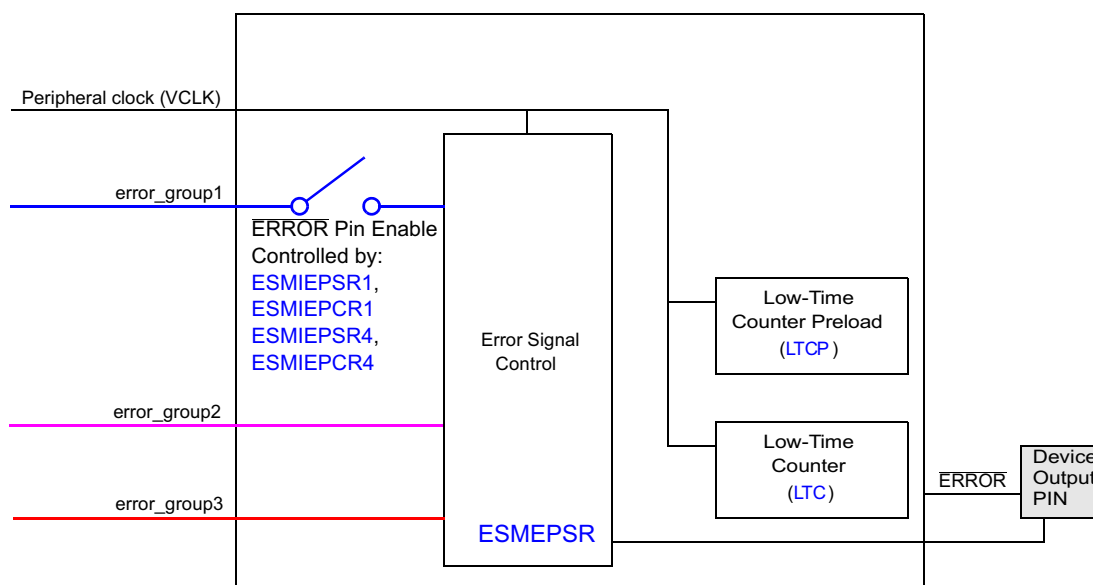

Table 12-1. ESM Interrupt and $\overline{\text{ERROR}}$ Pin Behavior

| Error Group | Interrupt to CPU | Interrupt Priority | $\overline{\text{ERROR}}$ Pin Response |
|-------------|---|---|--|
| 1 | Can be enabled or disabled for each channel | Can be selected as low/high-priority for each channel | $\overline{\text{ERROR}}$ pin action can be selected for each channel separately |
| 2 | Cannot be disabled | High priority | $\overline{\text{ERROR}}$ pin is asserted |
| 3 | No interrupt | NA | $\overline{\text{ERROR}}$ pin is asserted |

Figure 12-2 and Figure 12-3 show the interrupt response handling and $\overline{\text{ERROR}}$ pin response handling with register configuration. The total active time of the $\overline{\text{ERROR}}$ pin is controlled by the Low-Time Counter Preload register (LTCP) and the key register (ESMEPSR) as shown in Figure 12-3. See Section 12.2.2 for details.

Figure 12-2. Interrupt Response Handling

Figure 12-3. $\overline{\text{ERROR}}$ Pin Response Handling

12.2 Module Operation

This device has 128 error channels, divided into 3 different error groups. Please refer to the device datasheet for ESM channel assignment details.

The ESM module has error flags for each error channel. The error status registers ESMSR1, ESMSR4, ESMSR2, ESMSR3 provide status information on a pending error of Group1 (Channel 0-31), Group1 (Channel 32-63), Group2, and Group3, respectively. The ESMEPSR register provides the current $\overline{\text{ERROR}}$ status. The module also provides a status shadow register, ESMSSR2, which maintains the error flags of Group2 until power-on reset ($\overline{\text{PORRST}}$) is asserted. See [Section 12.2.1](#) for details of their behavior during power on reset and warm reset.

Once an error occurs, the ESM module will set the corresponding error flags. In addition, it can trigger an interrupt, $\overline{\text{ERROR}}$ pin outputs low depending on the ESM settings. Once the $\overline{\text{ERROR}}$ pin outputs low, a power on reset or a write of 5h to ESMEKR is required to release the ESM error pin back to normal state. See [Section 12.2.2](#) for details. The application can read the error status registers (ESMSR1, ESMSR4, ESMSR2, and ESMSR3) to debug the error. If an $\overline{\text{RST}}$ is triggered or the error interrupt has been served, the error flag of Group2 should be read from ESMSSR2 because the error flag in ESMSR2 will be cleared by $\overline{\text{RST}}$.

The user can also test the functionality of the $\overline{\text{ERROR}}$ pin by forcing an error. See [Section 12.2.3](#) for details.

12.2.1 Reset Behavior

Power on reset:

- $\overline{\text{ERROR}}$ pin behavior

When $\overline{\text{PORRST}}$ is active, the $\overline{\text{ERROR}}$ pin is in a high impedance state (output drivers disabled).

- Register behavior

After $\overline{\text{PORRST}}$, all registers in ESM module will be re-initialized to the default value. All the error status registers are cleared to zero.

Warm reset ($\overline{\text{RST}}$):

- $\overline{\text{ERROR}}$ pin behavior

During $\overline{\text{RST}}$, the $\overline{\text{ERROR}}$ pin is in "output active" state with pull-down disabled. The $\overline{\text{ERROR}}$ pin remains unchanged after $\overline{\text{RST}}$.

- Register behavior

After $\overline{\text{RST}}$, ESMSR1, ESMSR4, ESMSSR2, ESMSR3 and ESMEPSR register values remains unchanged. Since $\overline{\text{RST}}$ does not clear the critical failure registers, the user can read those registers to debug the failures after $\overline{\text{RST}}$ pin goes back to high.

After $\overline{\text{RST}}$, if one of the flags in ESMSR1 and ESMSR4 is set, the interrupt service routine will be called once the corresponding interrupt is enabled.

NOTE: ESMSR2 is cleared after $\overline{\text{RST}}$. The flag in ESMSR2 gets cleared when reading the appropriate vector in the ESMIOFFHR offset register. Reading ESMIOFFHR will not clear the ESMSR1, ESMSR4, and the shadow register ESMSSR2. Reading ESMIOFFLR will also not clear the ESMSR1 and ESMSR4.

12.2.2 $\overline{\text{ERROR}}$ Pin Timing

The $\overline{\text{ERROR}}$ pin is an active-low function. The state of the pin is also readable from $\overline{\text{ERROR}}$ Pin Status Register (ESMEPSR). The pin is in a high-impedance state during power-on reset. Once the ESM module drives the $\overline{\text{ERROR}}$ pin low, it remains in this state for the time specified by the Low-Time Counter Preload register (LTCPR). Based on the time period of the peripheral clock (VCLK), the total active time of the $\overline{\text{ERROR}}$ pin can be calculated as:

$$t_{\overline{\text{ERROR_low}}} = t_{\text{VCLK}} \times (\text{LTCP} + 1) \quad (23)$$

Once this period expires, the $\overline{\text{ERROR}}$ pin is set to high in case the reset of the $\overline{\text{ERROR}}$ pin was requested. This request is done by writing an appropriate key (5h) to the key register (ESMEKR) during the $\overline{\text{ERROR}}$ pin low time. Here are a few examples:

Example 1: ESM detects a failure and drives the $\overline{\text{ERROR}}$ pin low. No $\overline{\text{ERROR}}$ pin reset is requested. The $\overline{\text{ERROR}}$ pin continues outputting low until power on reset occurs.

Figure 12-4. $\overline{\text{ERROR}}$ Pin Timing - Example 1

Example 2: ESM detects a failure and drives the $\overline{\text{ERROR}}$ pin low. An $\overline{\text{ERROR}}$ pin reset request is received before $t_{\overline{\text{ERROR_low}}}$ expires. In this case, the $\overline{\text{ERROR}}$ pin is set to high immediately after $t_{\overline{\text{ERROR_low}}}$ expires.

Figure 12-5. $\overline{\text{ERROR}}$ Pin Timing - Example 2

Example 3: ESM detects a failure and drives the $\overline{\text{ERROR}}$ pin low. An $\overline{\text{ERROR}}$ pin reset request is received after $t_{\overline{\text{ERROR_low}}}$ expires. In this case, the $\overline{\text{ERROR}}$ pin is set to high immediately after $\overline{\text{ERROR}}$ pin reset request is received.

Figure 12-6. $\overline{\text{ERROR}}$ Pin Timing - Example 3

Example 4: ESM detects a failure and drives the $\overline{\text{ERROR}}$ pin low. Another failure occurs within the time the pin stays low. In this case, the low-time counter will be reset when the other failure occurs. In other words, $t_{\overline{\text{ERROR_low}}}$ should be counted from whenever the most recent failure occurs.

Figure 12-7. $\overline{\text{ERROR}}$ Pin Timing - Example 4

Example 5: The reset of the $\overline{\text{ERROR}}$ pin was requested by the software even before the failure occurs. In this case, the $\overline{\text{ERROR}}$ pin is set to high immediately after $t_{\overline{\text{ERROR_low}}}$ expires. This case is not recommended and should be avoided by the application.

Figure 12-8. $\overline{\text{ERROR}}$ Pin Timing - Example 5

Example 6: Failure1, then $\overline{\text{ERROR}}$ pin reset request, then Failure2 occurs before $\overline{\text{ERROR}}$ pin gets reset. In this case, the $\overline{\text{ERROR}}$ pin low-time is just extended (restarted) when the failure2 occurs and goes high when this count-down expires. There now is a scenario where the $\overline{\text{ERROR}}$ pin is high and the group2/3 status flag is set. To avoid this scenario, the application must write 5h followed by 0 to the ESM Error Key Register (ESMEKR). In this case, the $\overline{\text{ERROR}}$ pin will go high and then go low again to indicate the second failure.

12.2.3 Forcing an Error Condition

The error response generation mechanism is testable by software by forcing an error condition. This allows testing the $\overline{\text{ERROR}}$ pin functionality. By writing a dedicated key to the ESM Error Key Register (ESMEKR), the $\overline{\text{ERROR}}$ pin is set to low for the specified time. The following steps describe how to force an error condition:

1. Check $\overline{\text{ERROR}}$ Pin Status Register (ESMEPSR). This register must be 1 to switch into the error forcing mode.

The ESM module cannot be switched into the error forcing mode if a failure has already been detected in functional mode. The application command to switch to error forcing mode is ignored.

2. Write 5h to the ESM Error Key Register (ESMEKR). After that, the $\overline{\text{ERROR}}$ pin should output low (error force mode).

Once the application puts the ESM module in the error forcing mode, the $\overline{\text{ERROR}}$ pin cannot indicate the normal error functionality. If a failure occurs during this time, it gets still latched and the LTC is reset and stopped. The error output pin is already driven low on account of the error forcing mode. When the ESM is forced back to normal functional mode, the LTC becomes active and forces the $\overline{\text{ERROR}}$ pin low until the expiration of the LTC (see Figure 12-9).

3. Write 0 to the ESM Error Key Register (ESMEKR) back to the active normal mode.

If there are no errors detected while the ESM module is in the error forcing mode, the $\overline{\text{ERROR}}$ pin goes high immediately after exiting the error forcing mode.

Figure 12-9. $\overline{\text{ERROR}}$ Pin Timing - Example 7

12.3 Recommended Programming Procedure

During the initialization stage, the application code should follow the recommendations in [Figure 12-10](#) to initialize the ESM.

Figure 12-10. ESM Initialization

Once an error occurs, it can trigger an interrupt, $\overline{\text{ERROR}}$ pin outputs low depending on the ESM settings. Once the $\overline{\text{ERROR}}$ pin outputs low, a power on reset or a write of 5h to ESMEKR is required to release the ESM back to normal state. The application can read the error status registers (ESMSR1, ESMSR4, ESMSR2, and ESMSR3) to debug the error. If an $\overline{\text{RST}}$ is triggered or the error interrupt has been served, the error flag of Group2 should be read from ESMSR2 because the error flag in ESMSR2 will be cleared by $\overline{\text{RST}}$.

12.4 Control Registers

This section describes the ESM registers. Each register begins on a 32-bit word boundary. The registers support 32-bit, 16-bit, and 8-bit accesses. The base address for the registers is FFFF F500h.

Table 12-2. ESM Module Registers

| Address | Acronym | Register Description | Section |

| Bit | Field | Value | Description |
|------|------------|-------|--|
| 31-0 | INTLVLCCLR | 0 | Clear interrupt priority. Read in User and Privileged mode. Write in Privileged mode only. Read: Interrupt of channel x is mapped to low-level interrupt line. Write: Leaves the bit and the corresponding set bit in the ESMILSR1 register unchanged. |
| | | 1 | Read: Interrupt of channel x is mapped to high-level interrupt line. Write: Maps interrupt of channel x to low-level interrupt line and clears the corresponding set bit in the ESMILSR1 register. |

12.4.7 ESM Status Register 1 (ESMSR1)

This register is dedicated for Group1. Note that the ESMSR1 status register will get updated if an error condition occurs, regardless if the corresponding interrupt enable flag is set or not.

Figure 12-17. ESM Status Register 1 (ESMSR1)
[address = FFFF F518h]

LEGEND: R/W = Read/Write; W1CP = Write 1 to clear in privilege mode only; -n = value after reset/PORRST; X = Value unchanged

Table 12-9. ESM Status Register 1 (ESMSR1) Field Descriptions

| Bit | Field | Value | Description |
|------|-------|-------|--|
| 31-0 | ESF | 0 | Error Status Flag. Provides status information on a pending error. Read in User and Privileged mode. Write in Privileged mode only. Read: No error occurred; no interrupt is pending. Write: Leaves the bit unchanged. |
| | | 1 | Read: Error occurred; interrupt is pending. Write: Clears the bit. Note: After RST, if one of these flags are set and the corresponding interrupt are enabled, the interrupt service routine will be called. |

12.4.8 ESM Status Register 2 (ESMSR2)

This register is dedicated for Group2.

Figure 12-18. ESM Status Register 2 (ESMSR2)
[address = FFFF F51Ch]

LEGEND: R/W = Read/Write; W1CP = Write 1 to clear in privilege mode only; -n = value after reset

Table 12-10. ESM Status Register 2 (ESMSR2) Field Descriptions

| Bit | Field | Value | Description |
|------|-------|-------|---|
| 31-0 | ESF | 0 | Error Status Flag. Provides status information on a pending error. Read in User and Privileged mode. Write in Privileged mode only. Read: No error occurred; no interrupt is pending. Write: Leaves the bit unchanged. |
| | | 1 | Read: Error occurred; interrupt is pending. Write: Clears the bit. ESMSSR2 is not impacted by this action. Note: In normal operation, the flag gets cleared when reading the appropriate vector in the ESMIOFFHR offset register. Reading ESMIOFFHR will not clear the ESMSR1 and the shadow register ESMSSR2. |

12.4.9 ESM Status Register 3 (ESMSR3)

This register is dedicated for Group3.

| Bit | Field | Value | Description |
|-------|----------|-------|--|
| 63-32 | INTLVLCR | 0 | Clear interrupt level Read in User and Privileged mode. Write in Privileged mode only. Read: Interrupt of channel x is mapped to low-level interrupt line. Write: Leaves the bit and the corresponding set bit in the ESMILSR4 register unchanged. |
| | | 1 | Read: Interrupt of channel x is mapped to high-level interrupt line. Write: Maps interrupt of channel x to low-level interrupt line and clears the corresponding set bit in the ESMILSR4 register. |

12.4.23 ESM Status Register 4 (ESMSR4)

This register is dedicated for Group1.

Figure 12-33. ESM Status Register 4 (ESMSR4)
[address = FFFF F558h]

LEGEND: R/W = Read/Write; W1CP = Write 1 to clear in privilege mode only; -n = value after reset/PORRST; X = Value unchanged

Table 12-25. ESM Status Register 4 (ESMSR4) Field Descriptions

| Bit | Field | Value | Description |
|-------|-------|-------|--|
| 63-32 | ESF | 0 | Error Status Flag. Provides status information on a pending error. Read in User and Privileged mode. Write in Privileged mode only. Read: No error occurred; no interrupt is pending. Write: Leaves the bit unchanged. |
| | | 1 | Read: Error occurred; interrupt is pending. Write: Clears the bit. Note: After RST, if one of these flags are set and the corresponding interrupt are enabled, the interrupt service routine will be called. |

Real-Time Interrupt (RTI) Module

This chapter describes the functionality of the real-time interrupt (RTI) module. The RTI is designed as an operating system timer to support a real time operating system (RTOS).

NOTE: This chapter describes a superset implementation of the RTI module that includes features and functionality related to DMA, FlexRay, and Timbase control. These features are dependent on the device-specific feature content. Consult your device-specific datasheet to determine the applicability of these features to your device being used.

| Topic | Page |
|--|------------|
| 13.1 Overview | 447 |
| 13.2 Module Operation | 448 |
| 13.3 RTI Control Registers..... | 458 |

13.1 Overview

The real-time interrupt (RTI) module provides timer functionality for operating systems and for benchmarking code. The RTI module can incorporate several counters that define the timebases needed for scheduling in the operating system.

The timers also allow you to benchmark certain areas of code by reading the values of the counters at the beginning and the end of the desired code range and calculating the difference between the values.

In addition the RTI provides a mechanism to synchronize the operating system to the FlexRay communication cycle. Clock supervision allows for detection of issues on the FlexRay bus with an automatic switch to an internally generated timebase when a failure with the FlexRay timebase is detected.

13.1.1 Features

The RTI module has the following features:

- Two independent 64 bit counter blocks
- Four configurable compares for generating operating system ticks or DMA requests. Each event can be driven by either counter block 0 or counter block 1.
- One counter block usable for application synchronization to FlexRay network including clock supervision
- Fast enabling/disabling of events
- Two time stamp (capture) functions for system or peripheral interrupts, one for each counter block
- Digital windowed watchdog

13.1.2 Industry Standard Compliance Statement

This module is specifically designed to fulfill the requirements for OSEK (**O**ffene **S**ysteme und deren **S**chnittstellen für die **E**lektronik im **K**raftfahrzeug, or Open Systems and the Corresponding Interfaces for Automotive Electronics) as well as OSEK/time-compliant operating systems, but is not limited to it.

13.2 Module Operation

Figure 13-1 illustrates the high level block diagram of the RTI module.

The RTI module has two independent counter blocks for generating different timebases: counter block 0 and counter block 1. The two counter blocks provide the same basic functionality, but counter block 0 has the additional functionality of being able to work with the FlexRay Macrotick (NTU0) or Start of Cycle (NTU1) and perform clock supervision to detect a missing signal.

A compare unit compares the counters with programmable values and generates four independent interrupt or DMA requests on compare matches. Each of the compare registers can be programmed to be compared to either counter block 0 or counter block 1.

The following sections describe the individual functions in more detail.

Figure 13-1. RTI Block Diagram

13.2.1 Counter Operation

Each counter block consists of the following (see Figure 13-2):

- One 32-bit prescale counter (RTIUC0 or RTIUC1)
- One 32-bit free running counter (RTIFRC0 or RTIFRC1)

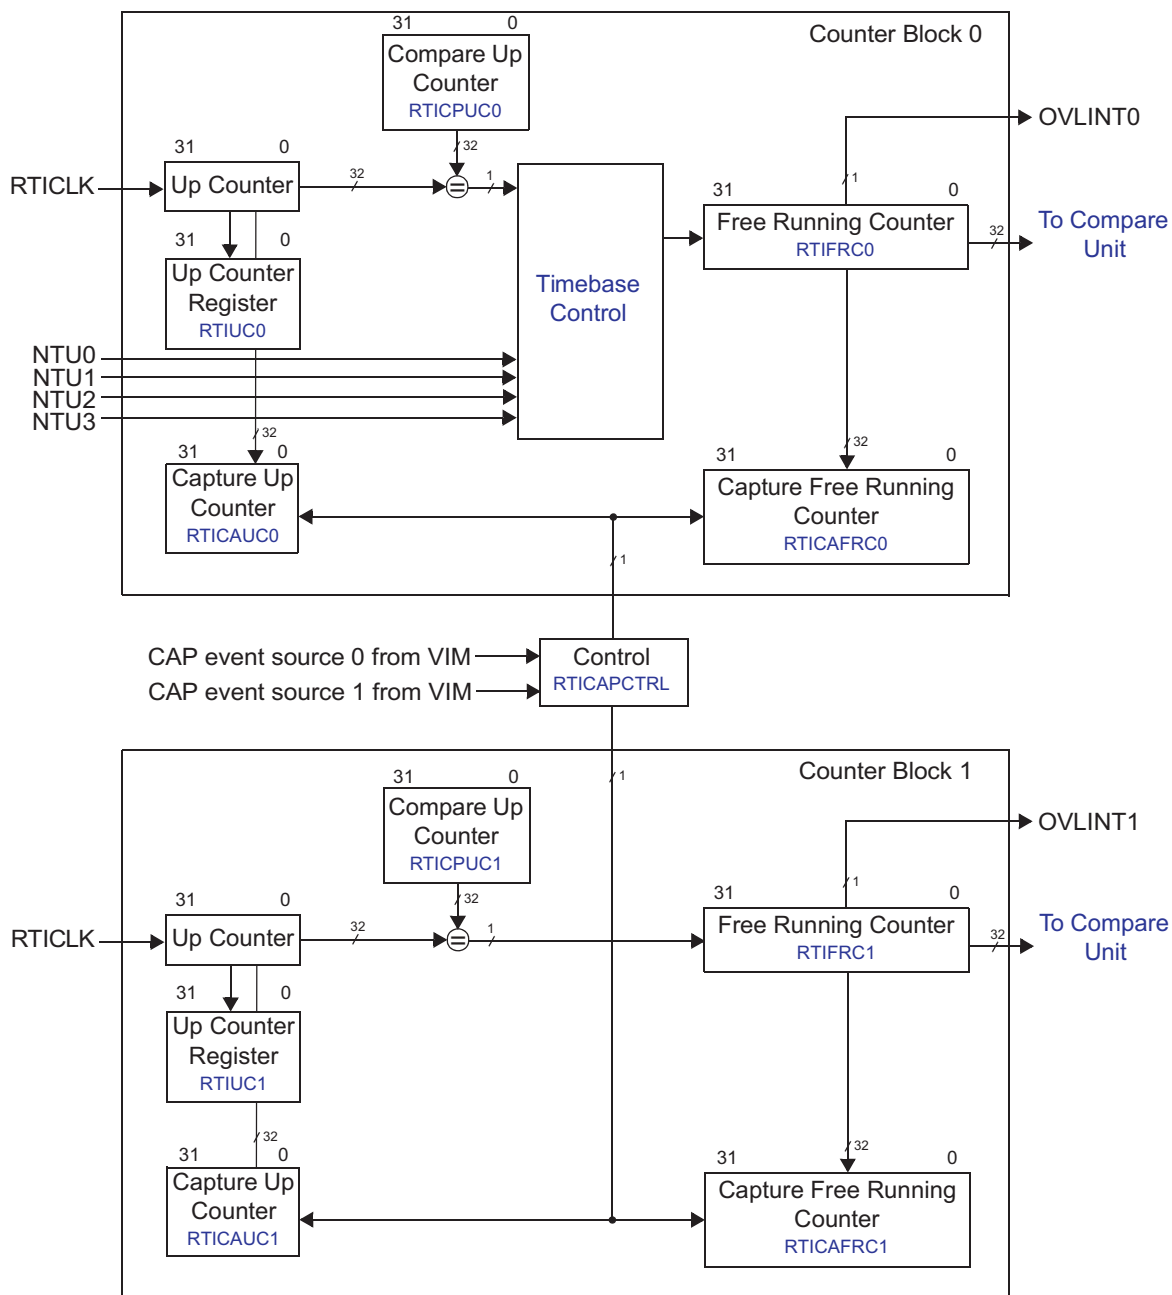

The RTIUC0/1 is driven by the RTICLK and counts up until the compare value in the compare up counter register (RTICPUC0 or RTICPUC1) is reached. When the compare matches, RTIFRC0/1 is incremented and RTIUC0/1 is reset to 0. If RTIFRC0/1 overflows, an interrupt is generated to the vectored interrupt manager (VIM). The overflow interrupt is not intended to generate the timebase for the operating system. See Section 13.2.2 for the timebase generation. The up counter together with the compare up counter value prescale the RTI clock. The resulting formula for the frequency of the free running counter (RTIFRC0/1) is:

$$f_{\text{RTIFRCx}} = \begin{cases} \frac{f_{\text{RTICLK}}}{\text{RTICPUCx} + 1} & \text{when RTICPUCx} \neq 0 \\ \frac{f_{\text{RTICLK}}}{2^{32} + 1} & \text{when RTICPUCx} = 0 \end{cases} \quad (24)$$

NOTE: Setting RTICPUCx equal to zero is not recommended. Doing so will hold the Up Counter at zero for two RTICLK cycles after it overflows from 0xFFFFFFFF to zero.

The counter values can be determined by reading the respective counter registers or by generating a hardware event which captures the counter value into the respective capture register. Both functions are described in the following sections.

Figure 13-2. Counter Block Diagram

13.2.1.1 Counter and Capture Read Consistency

Portions of the device internal databus are 32-bits wide. If the application wants to read the 64-bit counters or the 64-bit capture values, a certain order of 32-bit read operations needs to be followed. This is to prevent one counter incrementing in between the two separate read operations to both counters.

Reading the Counters

The free running counter (RTIFRCx) must be read first. This priority will ensure that in the cycle when the CPU reads RTIFRCx, the up counter value is stored in its counter register (RTIUCx). The second read has to access the up counter register (RTIUCx), which then holds the value which corresponds to the number of RTICLK cycles that have elapsed at the time reading the free running counter register (RTIFRCx).

NOTE: The up counters are implemented as shadow registers. Reading RTIUCx without having read RTIFRCx first will return always the same value. RTIUCx will only be updated when RTIFRCx is read.

Reading the Capture Values

The free running counter capture register (RTICAFRCx) must be read first. This priority will ensure that in the cycle when the CPU reads RTICAFRCx, the up counter value is stored in its counter register (RTICAUCx). The second read has to access the up counter register (RTICAUCx), which then holds the value captured at the time when reading the capture free running counter register (RTICAFRCx).

NOTE: The capture up counter registers are implemented as shadow registers. Reading RTICAUCx without having read RTICAFRCx first will return always the same value. RTICAUCx will only be updated when RTICAFRCx is read.

13.2.1.2 Capture Feature

Both counter blocks also provide a capture feature on external events. Two capture sources can trigger the capture event. The source triggering the block is configurable (RTICAPCTRL). The sources originate from the Vectored Interrupt Manager (VIM) and allow the generation of capture events when a peripheral modules has generated an interrupt. Any of the peripheral interrupts can be selected as the capture event in the VIM.

When an event is detected, RTIUCx and RTIFRCx are stored in the capture up counter (RTICAUCx) and capture free running counter (RTICAFRCx) registers. The read order of the captured values must be the same as the read order of the actual counters (see [Section 13.2.1.1](#)).

13.2.2 Interrupt/DMA Requests

There are four compare registers (RTICOMP_y) to generate interrupt requests to the VIM or DMA requests to the DMA controller. The interrupts can be used to generate different timebases for the operating system. Each of the compare registers can be configured to be compared to either RTIFRC0 or RTIFRC1. When the counter value matches the compare value, an interrupt is generated. To allow periodic interrupts, a certain value can be added to the compare value in RTICOMP_y automatically. This value is stored in the update compare register (RTIUDCP_y) and will be added after a compare is matched. The period of the generated interrupt/DMA request can be calculated with:

$$t_{COMPx} = t_{RTICLK} \times (RTICPUCy + 1) \times RTIUDCPy$$

if RTICPUC_y = 0,

$$t_{COMPx} = t_{RTICLK} \times (2^{32} + 1) \times RTIUDCPy$$

if RTIUDCP_y = 0,

$$t_{COMPx} = t_{RTICLK} \times (RTICPUCy + 1) \times 2^{32} \quad (25)$$

Figure 13-3. Compare Unit Block Diagram (shows only 1 of 4 blocks for simplification)

Another interrupt that can be generated is the overflow interrupt (OVLINTx) in case the RTIFRCx counter overflows.

The interrupts/DMA requests can be enabled in the RTISETINTENA register and disabled in the RTICLEARINTENA register. The RTIINTFLAG register shows the pending interrupts.

13.2.3 RTI Clocking

The counter blocks are clocked with RTICLK (for definition see [Section 2.4.2](#)). Counter block 0 can be clocked in addition by either the FlexRay Macrotick (NTU0) or the FlexRay Start of Cycle (NTU1).

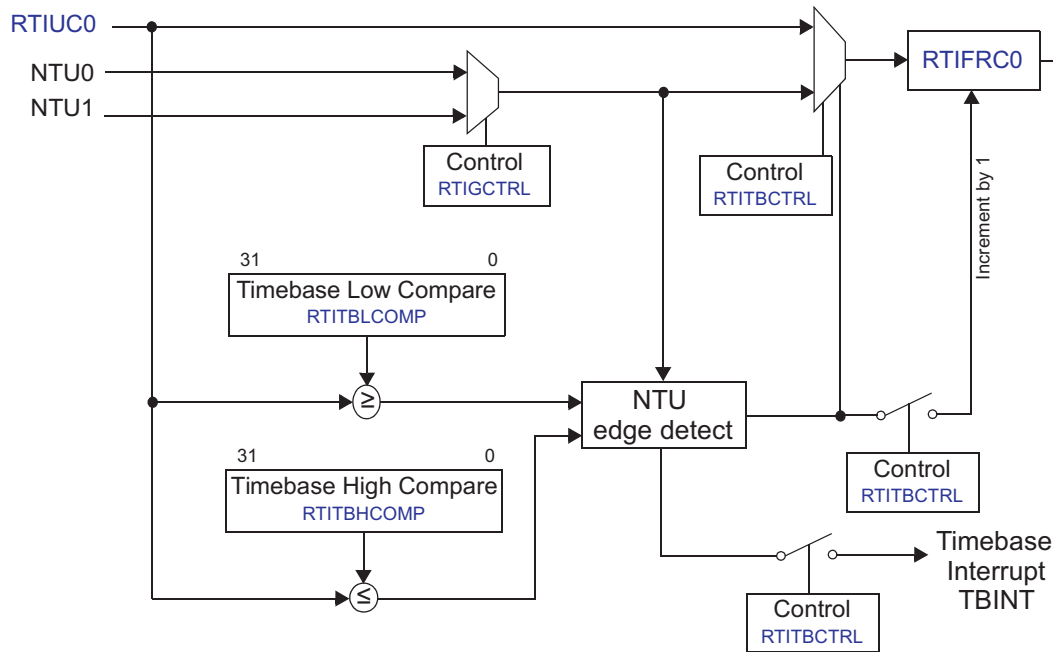

A clock supervision for the NTUx clocking scheme is implemented to avoid missing operating system ticks.

13.2.4 Synchronizing Timer Events to Network Time (NTU)

For applications which are participating on a time-triggered communication bus, it is often beneficial to synchronize the application or operating system to the network time. The RTI provides a feature to increment Free Running Counter 0 (RTIFRC0) by a periodic clock provided by the communication module. In this case two different clocks can be chosen. One is the FlexRay module Macrotick (NTU0) and the other is the Start of Cycle (NTU1) information of the same module.

The application has control over which clock (RTICLK, NTU0, NTU1) should be used for clocking RTIFRC0. If NTUx is used, a clock supervision circuit allows to monitor this clock and provides a fallback solution, should the clock be non-functional (missing). A too fast running NTUx cannot be detected.

RTIUC0 is utilized to monitor the NTUx signal. A detection window can be programmed in which a valid NTU clock pulse needs to occur. If no pulse is detected, the RTI automatically switches back to clock the Free Running Counter 0 with RTIUC0. In order to avoid a big jitter in the operating ticks, in case a switch back to RTIUC0 happens, RTICPUC0 should be set to a value so the clock frequency RTIUC0 outputs is approximately the same as the NTUx frequency.

Figure 13-4. Timebase Control

13.2.4.1 Detecting Clock Edges

To detect clock edges on the NTUx signal, the timebase low compare has to be set lower or equal than the value stored in the RTICPUC0 register and the timebase high compare has to be set higher than 0 and lower than the timebase low compare value. This effectively opens a window in which an edge of the NTUx signal is expected (see Figure 13-5). Outside this window, no edges will be detected. If no edge will occur inside the detection window, the multiplexer is switched to internal timebase. The application can select to generate a timebase interrupt (TBINT) and if the INC bit is set, also will automatically increment RTIFRC0 by one to compensate for the missed clock cycle of NTUx. If an edge occurs inside the window, RTIUC0 will be reset to synchronize the two timebases.

In order to make the edge detection work properly, the value in RTICPUC0 needs to be adapted so that RTIUC0 has a similar period as NTUx.

NOTE: To ensure the NTUx signal is properly detected, the NTUx period must be at least twice as long as the RTICLK period.

Figure 13-5. Clock Detection Scheme

13.2.4.2 Switching from Internal Source to External Source

If the application switches from an internal source to an external source, the two signals must be synchronized (see Figure 13-6). The synchronization will occur when the TBEXT bit is set. RTIUC0 will be reset and the edge detection circuit will be active for one (RTICPUC0 + RTITBHCOMP) period or until an edge is detected. If there is no pulse during this period, the source will be reset from an external clock source to an internal clock source. If an edge is detected, the windowed edge detection behavior will take place. Setting the TBEXT bit will not increment free running counter 0.

NOTE: If an external timebase is used, then the software must ensure that timebase low compare and timebase high compare are programmed to a valid state before switching TBEXT to an external source. This state is necessary to allow the timebase control circuit to operate correctly. The following condition must be met:

- $RTITBHCOMP < RTITBLCOMP + RTICPUC0$

RTITBHCOMP must be lower than RTICPUC0 because RTIUC0 will be reset if RTICPUC0 is reached. RTITBHCOMP will represent the number of RTICLK cycles from RTICPUC0 until the circuit switches to the internal timebase when no NTU edge is detected.

If an external timebase is used, RTIGCTRL[0] must be set to 1 (enable RTIUC0) to ensure that the timebase control circuit does not wait indefinitely for an incoming signal.

Figure 13-6 shows a timing example for the synchronization phase when the TBEXT bit is set.

Figure 13-6. Switch to NTUx

13.2.4.3 Switching from External Source to Internal Source

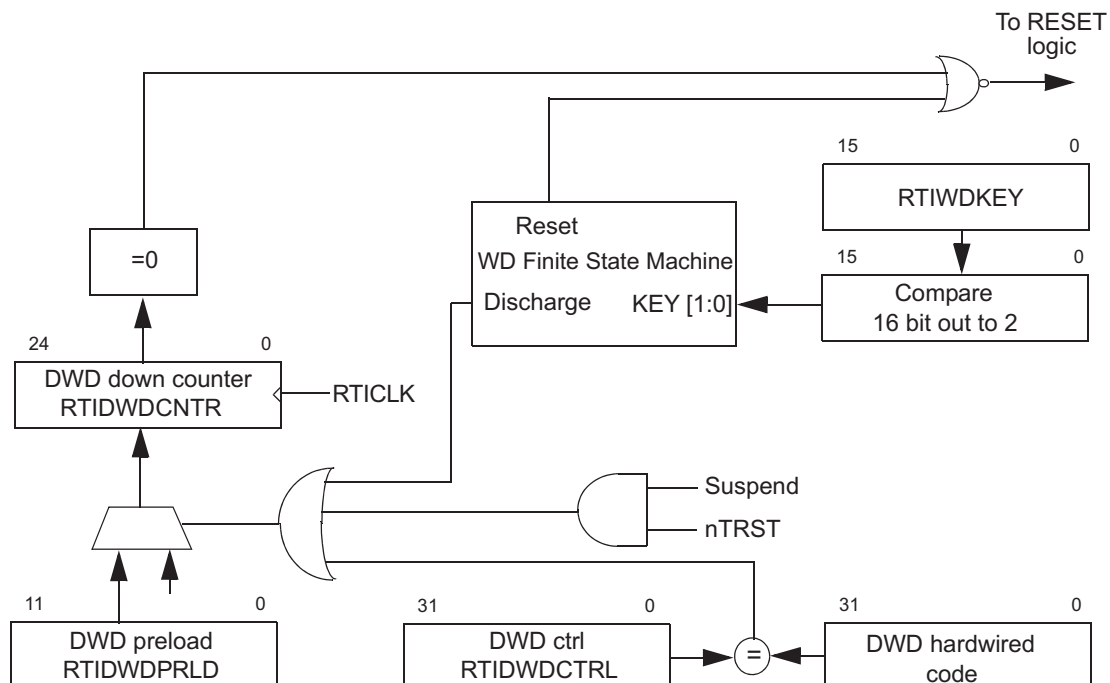

When the edge detection is active (TBEXT = 1) and no clock edge of NTUx is detected inside the programmed detection window, the RTI will automatically switch the timebase to RTIUC0. Figure 13-7 shows a timing example for a missing NTU signal. In the case where the INC bit is set, RTIFRC0 will automatically be incremented by one to compensate for the missed NTU pulse.

Setting TBEXT = 0 will also switch the clock source for RTIFRC0 to RTIUC0.

Figure 13-7. Missing NTUx Signal Example

13.2.5 Digital Watchdog (DWD)

The digital watchdog (DWD) is an optional safety diagnostic which can detect a runaway CPU and generate either a reset or NMI (non-maskable interrupt) response. It generates resets or NMIs after a programmable period, or if no correct key sequence was written to the RTIWDKEY register. [Figure 13-8](#) illustrates the DWD.

Figure 13-8. Digital Watchdog

13.2.5.1 Digital Watchdog (DWD)

The DWD is disabled by default. If it should be used, it must be enabled by writing a 32-bit value to the RTIDWDCTRL register.

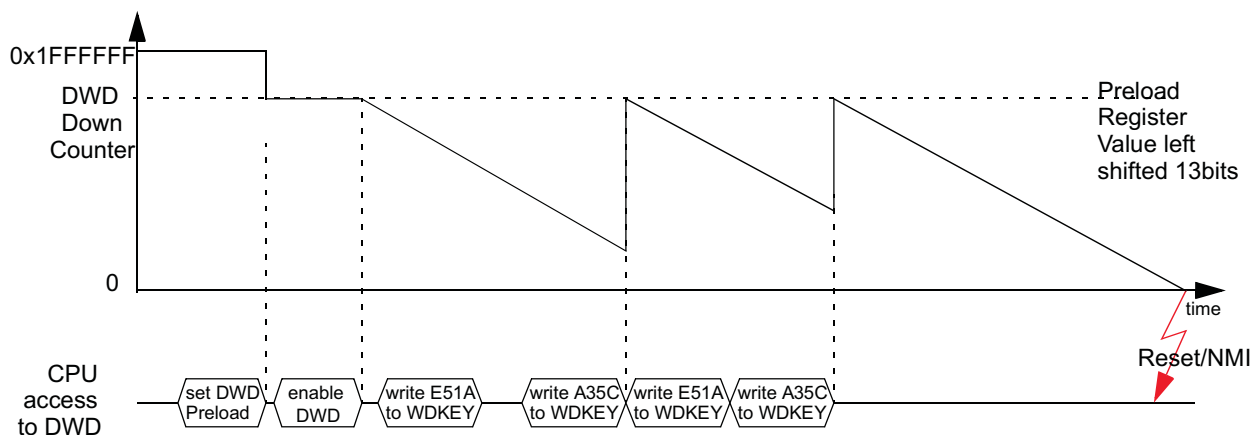

NOTE: Once the DWD is enabled, it cannot be disabled except by system reset or power on reset.

If the correct key sequence is written to the RTIWDKEY register (0xE51A followed by 0xA35C), the 25-bit DWD down counter is reloaded with the left justified 12-bit preload value stored in RTIDWDPRLD. If an incorrect value is written, a watchdog reset or NMI will occur immediately. A reset or NMI will also be generated when the DWD down counter is decremented to 0.

While the device is in suspend mode (halting debug mode), the DWD down counter keeps the value it had when entering suspend mode.

The DWD down counter will be decremented with the RTICLK frequency.

Figure 13-9. DWD Operation

The expiration time of the DWD down counter can be determined with the following equation:

$$t_{exp} = (DWDPRLD + 1) \times 2^{13}/RTICLK$$

where

$$DWDPRLD = 0 \dots 4095$$

NOTE: Care should be taken to ensure that the CPU write to the watchdog register is made allowing time for the write to propagate to the RTI.

13.2.5.2 Digital Windowed Watchdog (DWWD)

In addition to the time-out boundary configurable via the digital watchdog discussed in [Section 13.2.5.1](#), for enhanced safety metrics it is desirable to check for a watchdog "pet" within a time window rather than using a single time threshold. This is enabled by the digital windowed watchdog (DWWD) feature.

- Functional Behavior

The DWWD opens a configurable time window in which the watchdog must be serviced. Any attempt to service the watchdog outside this time window, or a failure to service the watchdog in this time window, will cause the watchdog to generate either a reset or a NMI to the CPU. This is controlled by configuring the RTIWWDRXNCTRL register. As with the DWD, the DWWD is disabled after power on reset. When the DWWD is configured to generate a non-maskable interrupt on a window violation, the watchdog counter continues to count down. The NMI handler needs to clear the watchdog violation status flag(s) and then

service the watchdog by writing the correct sequence in the watchdog key register. This service will cause the watchdog counter to get reloaded from the preload value and start counting down. If the NMI handler does not service the watchdog in time, it could count down all the way to zero and wrap around. If the NMI Handler does not service the watchdog in time, the NMI gets generated continuously, each time the counter counts to '0'.

The DWWD uses the Digital Watchdog (DWD) preload register (RTIDWDPRLD) setting to define the end-time of the window. The start-time of the window is defined by a window size configuration register(RTIWWDSIZECTRL).

The default window size is set to 100%, which corresponds to the DWD functionality of a time-out-only watchdog. The window size can be selected (through register RTIWWDSIZECTRL) from among 100%, 50%, 25%, 12.5%, 6.25% and 3.125% as shown in Figure 13-10. The window with the respective size will be opened before the end of the DWD expiration. The user has to serve the watchdog in the window. Otherwise, a reset or NMI will generate. Figure 13-11 shows an DWWD operation example (25% window).

- Configuration of DWWD

The DWWD preload value (same as DWD preload) can only be configured when the DWWD counter is disabled. The window size and watchdog reaction to a violation can be configured even after the watchdog has been enabled. Any changes to the window size and watchdog reaction configurations will only take effect after the next servicing of the DWWD. This feature can be utilized to dynamically set windows of different sizes based on task execution time, adding a program sequence element to the diagnostic which can improve fault coverage.

Figure 13-10. Digital Windowed Watchdog Timing Example

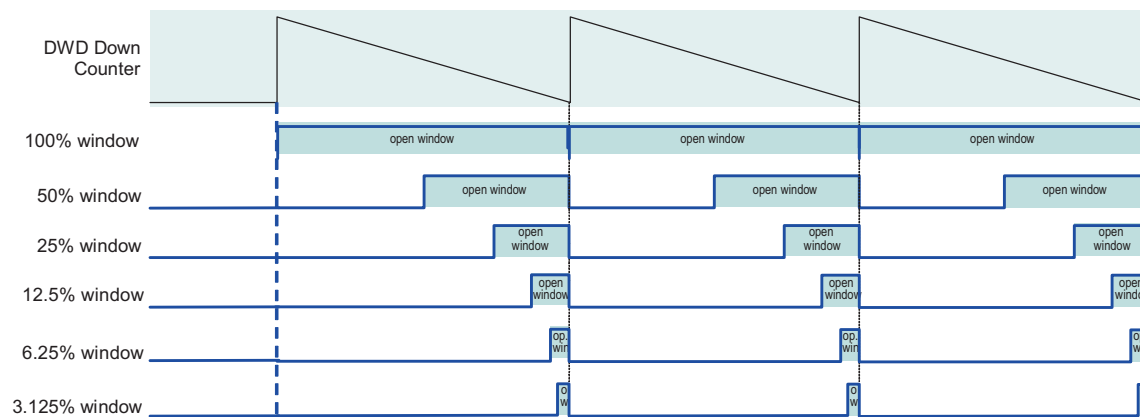

Figure 13-11. Digital Windowed Watchdog Operation Example (25% Window)

13.2.6 Low Power Modes

Low power modes allow the trade off of the current used during low power versus functionality and fast wakeup response. All low power modes have the following characteristics:

- CPU and system clocks are disabled.
- Flash banks and pump are in sleep mode.
- All peripheral modules are in low power modes and the clocks are disabled (exceptions to this may occur and would be documented in the specific device data sheet).

Flexibility in enabling and disabling clocks allows for many different low-power modes (see [Section 2.4.3](#)).

The operation of the RTI Module is guaranteed in Run, Doze and Snooze modes. In Sleep mode, all clocks will be switched off and the RTI will not work.

In Doze and Snooze modes, the RTI is active and is able to wake up the device with compare, timebase and overflow interrupts. The compare interrupts can be used to periodically wake up the device. The overflow interrupt can be used to notify the operating system that a counter overflow has occurred. Capturing events generated by the Vectored Interrupt Module (VIM) is also possible since, in both of these low power modes, the peripheral modules are able to generate interrupts that can trigger capture events. Capturing events while in Sleep mode is not supported as the clock to the RTI is not active.

When the device is put into low power mode, the peripheral which is generating the external clock NTU is no longer active, and the timebase control circuitry has to switch to an internal clocking scheme when it detects a missing clock on NTU. The timebase interrupt will wake up the device and the application software has to adapt the periodic interrupt generation to the internal clock source.

DMA transfers will be disabled, and DMA requests will not be generated after device wakeup since the DMA controller will be powered down.

NOTE: RTICK in Doze Mode

In the special case of Doze Mode with PLL off, RTICK might have a different period than with PLL enabled since RTICK will be derived from the oscillator output. It has to be ensured that the VCLK to RTICK ratio is at least 3:1.

13.2.7 Halting Debug Mode Behaviour

Once the system enters halting debug mode, the behavior of the RTI depends on the COS (continue on suspend) bit. If the bit is cleared and halting debug mode is active, all counters will stop operation. If the bit is set to one, all counters will be clocked normally and the RTI will work like in normal mode. However, if the external timebase (NTU) is used and the system is in halting debug mode, the timebase control circuit will switch to internal timebase once it detects the missing NTU signal of the suspended communication controller. This will be signaled with an TBINT interrupt so that software can resynchronize after the device exits halting debug mode.

13.3 RTI Control Registers

[Table 13-1](#) provides a summary of the registers. The registers support 8-bit, 16-bit, and 32-bit writes. The offset is relative to the associated peripheral select. See the following sections for detailed descriptions of the registers. The base address for the control registers is FFFF FC00h. The address locations not listed are reserved.

Table 13-1. RTI Registers

| Offset | Acronym | Register Description | Section |
|--------|-----------------|--|---------------------------------|
| 00h | RTIGCTRL | RTI Global Control Register | Section 13.3.1 |

NOTE: Writes to Reserved registers may clear the pending RTI interrupt.

13.3.1 RTI Global Control Register (RTIGCTRL)

The global control register starts/stops the counters and selects the signal compared with the timebase control circuit. This register is shown in [Figure 13-12](#) and described in [Table 13-2](#).

Figure 13-12. RTI Global Control Register (RTIGCTRL) [offset = 00]

| | | | | | |
|----------|----------|----|----|--------|--------|
| 31 | | 20 | 19 | | 16 |
| Reserved | | | | NTUSEL | |
| R-0 | | | | R/WP-0 | |
| 15 | 14 | | 2 | 1 | 0 |
| COS | Reserved | | | CNT1EN | CNT0EN |
| R/WP-0 | R-0 | | | R/WP-0 | R/WP-0 |

LEGEND: R/W = Read/Write; R = Read only; WP = Write in privileged mode only; -n = value after reset

Table 13-2. RTI Global Control Register (RTIGCTRL) Field Descriptions

| Bit | Field | Value | Description |
|-------|----------|--|--|
| 31-20 | Reserved | 0 | Reads return 0. Writes have no effect. |
| 19-16 | NTUSEL | 0h 5h Ah Fh All other values | Select NTU signal. These bits determine which NTU input signal is used as external timebase NTU0 NTU1 NTU2 NTU3 Tied to 0 |
| 15 | COS | 0 1 | Continue on suspend. This bit determines if both counters are stopped when the device goes into halting debug mode or if they continue counting. Counters are stopped while in halting debug mode. Counters are running while in halting debug mode. |
| 14-2 | Reserved | 0 | Reads return 0. Writes have no effect. |
| 1 | CNT1EN | 0 1 | Counter 1 enable. This bit starts and stops counter block 1 (RTIUC1 and RTIFRC1). Counter block 1 is stopped. Counter block 1 is running. |
| 0 | CNT0EN | 0 1 | Counter 0 enable. This bit starts and stops counter block 0 (RTIUC0 and RTIFRC0). Counter block 0 is stopped. Counter block 0 is running. |

NOTE: If the application uses the timebase circuit for synchronization between the communications controller and the operating system and the device enters halting debug mode, the synchronization may be lost depending on the COS setting in the RTI module and the halting debug mode behavior of the communications controller.

13.3.2 RTI Timebase Control Register (RTITBCTRL)

The timebase control register selects if the free running counter 0 is incremented by RTICLK or NTU. This register is shown in [Figure 13-13](#) and described in [Table 13-3](#).

Figure 13-13. RTI Timebase Control Register (RTITBCTRL) [offset = 04h]

| | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
|----------|--|--|--|--|--|--|--|--|--|--|--|--|--|--------|---|---|--------|--|--|--|--|--|--|--|--|--|--|--|---|

LEGEND: R/W = Read/Write; R = Read only; WP = Write in privileged mode only; -n = value after reset

Table 13-3. RTI Timebase Control Register (RTITBCTRL) Field Descriptions

| Bit | Field | Value | Description |
|------|----------|--------|---|
| 31-2 | Reserved | 0 | Reads return 0. Writes have no effect. |
| 1 | INC | 0 1 | Increment free running counter 0. This bit determines whether the free running counter 0 (RTIFRC0) is automatically incremented if a failing clock on the NTU signal is detected. RTIFRC0 will not be incremented on a failing external clock. RTIFRC0 will be incremented on a failing external clock. |
| 0 | TBEXT | 0 1 | Timebase external. This bit selects whether the free running counter 0 (RTIFRC0) is clocked by the internal up counter 0 (RTIUC0) or from the external signal NTU. Setting the TBEXT bit from 0 to 1 will not increment RTIFRC0, since RTIUC0 is reset. When the timebase supervisor circuit detects a missing clock edge, then the TBEXT bit is reset. Only the software can select whether the external signal should be used. RTIUC0 clocks RTIFRC0. NTU clocks RTIFRC0. |

13.3.3 RTI Capture Control Register (RTICAPCTRL)

The capture control register controls the capture source for the counters. This register is shown in [Figure 13-14](#) and described in [Table 13-4](#).

Figure 13-14. RTI Capture Control Register (RTICAPCTRL) [offset = 08h]

LEGEND: R/W = Read/Write; R = Read only; WP = Write in privileged mode only; -n = value after reset

Table 13-4. RTI Capture Control Register (RTICAPCTRL) Field Descriptions

| Bit | Field | Value | Description |
|------|----------|-------|--|
| 31-2 | Reserved | 0 | Reads return 0. Writes have no effect. |
| 1 | CAPCNTR1 | 0 | Capture counter 1. This bit determines which external interrupt source triggers a capture event of RTIUC1 and RTIFRC1. |
| | | 0 | Capture of RTIUC1/ RTIFRC1 is triggered by capture event source 0. |
| | | 1 | Capture of RTIUC1/ RTIFRC1 is triggered by capture event source 1. |
| 0 | CAPCNTR0 | 0 | Capture counter 0. This bit determines which external interrupt source triggers a capture event of RTIUC0 and RTIFRC0. |
| | | 0 | Capture of RTIUC0/ RTIFRC0 is triggered by capture event source 0. |
| | | 1 | Capture of RTIUC0/ RTIFRC0 is triggered by capture event source 1. |

13.3.4 RTI Compare Control Register (RTICOMPCTRL)

The compare control register controls the source for the compare registers. This register is shown in [Figure 13-15](#) and described in [Table 13-5](#).

Figure 13-15. RTI Compare Control Register (RTICOMPCTRL) [offset = 0Ch]

LEGEND: R/W = Read/Write; R = Read only; WP = Write in privileged mode only; -n = value after reset

Table 13-5. RTI Compare Control Register (RTICOMPCTRL) Field Descriptions

| Bit | Field | Value | Description |
|-------|----------|--------|---|
| 31-13 | Reserved | 0 | Reads return 0. Writes have no effect. |
| 12 | COMPSEL3 | 0 1 | Compare select 3. This bit determines the counter with which the compare value held in compare register 3 (RTICOMP3) is compared. Value will be compared with RTIFRC0. Value will be compared with RTIFRC1. |
| 11-9 | Reserved | 0 | Reads return 0. Writes have no effect. |
| 8 | COMPSEL2 | 0 1 | Compare select 2. This bit determines the counter with which the compare value held in compare register 2 (RTICOMP2) is compared. Value will be compared with RTIFRC0. Value will be compared with RTIFRC1. |
| 7-5 | Reserved | 0 | Reads return 0. Writes have no effect. |
| 4 | COMPSEL1 | 0 1 | Compare select 1. This bit determines the counter with which the compare value held in compare register 1 (RTICOMP1) is compared. Value will be compared with RTIFRC0. Value will be compared with RTIFRC1. |
| 3-1 | Reserved | 0 | Reads return 0. Writes have no effect. |
| 0 | COMPSEL0 | 0 1 | Compare select 0. This bit determines the counter with which the compare value held in compare register 0 (RTICOMP0) is compared. Value will be compared with RTIFRC0. Value will be compared with RTIFRC1. |

13.3.5 RTI Free Running Counter 0 Register (RTIFRC0)

The free running counter 0 register holds the current value of free running counter 0. This register is shown in [Figure 13-16](#) and described in [Table 13-6](#).

Figure 13-16. RTI Free Running Counter 0 Register (RTIFRC0) [offset = 10h]

| | | |

| 15 | | 0 |
| FRC0 | | |
| R/WP-0 | | |

LEGEND: R/W = Read/Write; R = Read only; WP = Write in privileged mode only; -n = value after reset

Table 13-6. RTI Free Running Counter 0 Register (RTIFRC0) Field Descriptions

| Bit | Field | Value | Description |
|------|-------|--------------|--|
| 31-0 | FRC0 | 0-FFFF FFFFh | Free running counter 0. This registers holds the current value of the free running counter 0. A read of this counter returns the current value of the counter. The counter can be preset by writing (in privileged mode only) to this register. The counter increments then from this written value upwards. Note: If counters must be preset, they must be disabled in the RTIGCTRL register to ensure consistency between RTIUC0 and RTIFRC0. |

13.3.6 RTI Up Counter 0 Register (RTIUC0)

The up counter 0 register holds the current value of prescale counter. This register is shown in [Figure 13-17](#) and described in [Table 13-7](#).

Figure 13-17. RTI Up Counter 0 Register (RTIUC0) [offset = 14h]

| R/WP-0 | | |

LLEGEND: R/W = Read/Write; R = Read only; WP = Write in privileged mode only; -n = value after reset

Table 13-7. RTI Up Counter 0 Register (RTIUC0) Field Descriptions

| Bit | Field | Value | Description |
|------|-------|--------------|--|
| 31-0 | UC0 | 0-FFFF FFFFh | Up counter 0. This register holds the current value of the up counter 0 and prescales the RTI clock. It will be only updated by a previous read of free running counter 0 (RTIFRC0). This method of updating effectively gives a 64-bit read of both counters, without having the problem of a counter being updated between two consecutive reads on up counter 0 (RTIUC0) and free running counter 0 (RTIFRC0). A read of this counter returns the value of the counter at the time RTIFRC0 was read. A write to this counter presets it with a value. The counter then increments from this written value upwards. Note: If counters must be preset, they must be disabled in the RTIGCTRL register to ensure consistency between RTIUC0 and RTIFRC0. Note: If the preset value is bigger than the compare value stored in register RTICPUC0, then it can take a long time until a compare matches, since RTIUC0 has to count up until it overflows. |

13.3.7 RTI Compare Up Counter 0 Register (RTICPUC0)

The compare up counter 0 register holds the value to be compared with prescale counter 0 (RTIUC0). This register is shown in [Figure 13-18](#) and described in [Table 13-8](#).

Figure 13-18. RTI Compare Up Counter 0 Register (RTICPUC0) [offset = 18h]

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 13-8. RTI Compare Up Counter 0 Register (RTICPUC0) Field Descriptions

| Bit | Field | Value | Description |
|------|-------|--------------|---|
| 31-0 | CPUC0 | 0-FFFF FFFFh | <p>Compare up counter 0. This register holds the value that is compared with the up counter 0. When the compare shows a match, the free running counter 0 (RTIFRC0) is incremented. RTIUC0 is set to 0 when the counter value matches the RTICPUC0 value. The value set in this register prescales the RTI clock.</p> <p>If CPUC0 = 0, then $f_{\text{RC0}} = \text{RTICLK} / (2^{32} + 1)$ (Setting CPUC0 equal to 0 is not recommended. Doing so will hold the Up Counter at 0 for 2 RTICLK cycles after it overflows from FFFF FFFFh to 0.)</p> <p>If CPUC0 ≠ 0, then $f_{\text{RC0}} = \text{RTICLK} / (\text{RTICPUC0} + 1)$</p> <p>A read of this register returns the current compare value.</p> <p>A write to this register:</p> <ul style="list-style-type: none"> If TBEXT = 0, the compare value is updated. If TBEXT = 1, the compare value is unchanged. |

13.3.8 RTI Capture Free Running Counter 0 Register (RTICAFRC0)

The capture free running counter 0 register holds the free running counter 0 on external events. This register is shown in [Figure 13-19](#) and described in [Table 13-9](#).

Figure 13-19. RTI Capture Free Running Counter 0 Register (RTICAFRC0) [offset = 20h]

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 13-9. RTI Capture Free Running Counter 0 Register (RTICAFRC0) Field Descriptions

| Bit | Field | Value | Description |
|------|--------|--------------|---|

| 31-0 | CAUC0 | 0-FFFF FFFFh | <p>Capture up counter 0. This register captures the current value of the up counter 0 (RTIUC0) when an event occurs, controlled by the external capture control block.</p> <p>Note: The read sequence must be the same as with RTIUC0 and RTIFRC0. Therefore, the RTICAFRC0 register must be read before the RTICAUC0 register is read. This sequence ensures that the value of the RTICAUC0 register is the corresponding value to the RTICAFRC0 register, even if another capture event happens in between the two reads.</p> <p>A read of this register returns the value of RTIUC0 on a capture event.</p> |

13.3.10 RTI Free Running Counter 1 Register (RTIFRC1)

The free running counter 1 register holds the current value of the free running counter 1. This register is shown in [Figure 13-21](#) and described in [Table 13-11](#).

Figure 13-21. RTI Free Running Counter 1 Register (RTIFRC1) [offset = 30h]

|------|-------|--------------|--|
| 31-0 | FRC1 | 0-FFFF FFFFh | <p>Free running counter 1. This register holds the current value of the free running counter 1 and will be updated continuously.</p> <p>A read of this register returns the current value of the counter.</p> <p>A write to this register presets the counter. The counter increments then from this written value upwards.</p> <p>Note: If counters must be preset, they must be disabled in the RTIGCTRL register to ensure consistency between RTIUC1 and RTIFRC1.</p> |

13.3.11 RTI Up Counter 1 Register (RTIUC1)

The up counter 1 register holds the current value of the prescale counter 1. This register is shown in [Figure 13-22](#) and described in [Table 13-12](#).

Figure 13-22. RTI Up Counter 1 Register (RTIUC1) [offset = 34h]

LEGEND: R/W = Read/Write; R = Read only; WP = Write in privileged mode only; -n = value after reset

Table 13-12. RTI Up Counter 1 Register (RTIUC1) Field Descriptions

| Bit | Field | Value | Description |
|------|-------|--------------|---|
| 31-0 | UC1 | 0-FFFF FFFFh | <p>Up counter 1. This register holds the current value of the up counter 1 and prescales the RTI clock. It will be only updated by a previous read of free running counter 1 (RTIFRC1). This method of updating effectively gives a 64-bit read of both counters, without having the problem of a counter being updated between two consecutive reads on RTIUC1 and RTIFRC1.</p> <p>A read of this register will return the value of the counter when the RTIFRC1 was read.</p> <p>A write to this register presets the counter. The counter then increments from this written value upwards.</p> <p>Note: If counters must be preset, they must be disabled in the RTIGCTRL register to ensure consistency between RTIUC1 and RTIFRC1.</p> <p>Note: If the preset value is bigger than the compare value stored in register RTICPUC1, then it can take a long time until a compare matches, since RTIUC1 has to count up until it overflows.</p> |

13.3.12 RTI Compare Up Counter 1 Register (RTICPUC1)

The compare up counter 1 register holds the value compared with prescale counter 1. This register is shown in [Figure 13-23](#) and described in [Table 13-13](#).

Figure 13-23. RTI Compare Up Counter 1 Register (RTICPUC1) [offset = 38h]

LEGEND: R/W = Read/Write; R = Read only; WP = Write in privileged mode only; -n = value after reset

Table 13-13. RTI Compare Up Counter 1 Register (RTICPUC1) Field Descriptions

| Bit | Field | Value | Description |
|------|-------|--------------|--|
| 31-0 | CPUC1 | 0-FFFF FFFFh | <p>Compare up counter 1. This register holds the compare value, which is compared with the up counter 1. When the compare matches, the free running counter 1 (RTIFRC1) is incremented. The up counter is cleared to 0 when the counter value matches the CPUC1 value. The value set in this prescales the RTI clock according to the following formula:</p> <p>If CPUC1 = 0, then $f_{FRC1} = RTICLK / (2^{32} + 1)$ (Setting CPUC1 equal to 0 is not recommended. Doing so will hold the Up Counter at 0 for 2 RTICLK cycles after it overflows from FFFF FFFFh to 0.)</p> <p>If CPUC1 \neq 0, then $f_{FRC1} = RTICLK / (RTICPUC1 + 1)$</p> <p>A read of this register returns the current compare value. A write to this register updates the compare value.</p> |

13.3.13 RTI Capture Free Running Counter 1 Register (RTICAFRC1)

The capture free running counter 1 register holds the current value of free running counter 1 on external events. This register is shown in [Figure 13-24](#) and described in [Table 13-14](#).

Figure 13-24. RTI Capture Free Running Counter 1 Register (RTICAFRC1) [offset = 40h]

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

| Bit | Field | Value | Description |
|------|--------|--------------|---|
| 31-0 | CAFRC1 | 0-FFFF FFFFh | Capture free running counter 1. This register captures the current value of the free running counter 1 (RTIFRC1) when an event occurs, controlled by the external capture control block. A read of this register returns the value of RTIFRC1 on a capture event. |

13.3.14 RTI Capture Up Counter 1 Register (RTICAUC1)

The capture up counter 1 register holds the current value of prescale counter 1 on external events. This register is shown in [Figure 13-25](#) and described in [Table 13-15](#).

Figure 13-25. RTI Capture Up Counter 1 Register (RTICAUC1) [offset = 44h]

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 13-15. RTI Capture Up Counter 1 Register (RTICAUC1) Field Descriptions

| Bit | Field | Value | Description |
|------|-------|--------------|--|
| 31-0 | CAUC1 | 0-FFFF FFFFh | Capture up counter 1. This register captures the current value of the up counter 1 (RTIUC1) when an event occurs, controlled by the external capture control block. Note: The RTICAFRC1 register must be read before the RTICAUC1 register is read. This sequence ensures that the value of the RTICAUC1 register is the corresponding value to the RTICAFRC1 register, even if another capture event happens in between the two reads. A read of this register returns the value of RTIUC1 on a capture event. |

13.3.15 RTI Compare 0 Register (RTICOMP0)

The compare 0 register holds the value to be compared with the counters. This register is shown in [Figure 13-26](#) and described in [Table 13-16](#).

Figure 13-26. RTI Compare 0 Register (RTICOMP0) [offset = 50h]

| Bit | Field | Value | Description |
|------|-------|--------------|---|
| 31-0 | COMP0 | 0-FFFF FFFFh | Compare 0. This registers holds a value that is compared with the counter selected in the compare control logic. If RTIFRC0 or RTIFRC1, depending on the counter selected, matches the compare value, an interrupt is flagged. With this register it is also possible to initiate a DMA request. A read of this register will return the current compare value. A write to this register (in privileged mode only) will update the compare register with a new compare value. |

13.3.16 RTI Update Compare 0 Register (RTIUDCP0)

The update compare 0 register holds the value to be added to the compare register 0 value on a compare match. This register is shown in [Figure 13-27](#) and described in [Table 13-17](#).

Figure 13-27. RTI Update Compare 0 Register (RTIUDCP0) [offset = 54h]

Table 13-25. RTI Timebase High Compare Register (RTITBHCOMP) Field Descriptions

| Bit | Field | Value | Description |
|------|---------|--------------|--|
| 31-0 | TBHCOMP | 0-FFFF FFFFh | Timebase high compare value. This value determines when the edge detection circuit will stop monitoring the NTU signal. It will be compared with RTIUC0. RTITBHCOMP must be less than RTICPUC0 because RTIUC0 will be reset when RTICPUC0 is reached. Example: The NTU edge detection circuit should be active ± 10 RTICLK cycles around RTICPUC0. <ul style="list-style-type: none"> RTICPUC0 = 0050h RTITBLCOMP = 0046h RTITBHCOMP = 0009h A read of this register will return the current compare value. A write to this register has the following effects: If TBEXT = 0: The compare value is updated. If TBEXT = 1: The compare value is not changed. |

13.3.25 RTI Set Interrupt Enable Register (RTISETINTENA)

This register prevents the necessity of a read-modify-write operation if a particular interrupt should be enabled. This register is shown in [Figure 13-36](#) and described in [Table 13-26](#).

| 7-4 | Reserved | 0 | Reads return 0. Writes have no effect. |
| 3 | CLEARINT3 | 0 | Clear compare interrupt 3. <i>Read:</i> Interrupt is disabled. <i>Write:</i> Corresponding bit is unchanged. |
| | | 1 | <i>Read:</i> Interrupt is enabled. <i>Write:</i> Interrupt is disabled. |
| 2 | CLEARINT2 | 0 | Clear compare interrupt 2. <i>Read:</i> Interrupt is disabled. <i>Write:</i> Corresponding bit is unchanged. |
| | | 1 | <i>Read:</i> Interrupt is enabled. <i>Write:</i> Interrupt is disabled. |
| 1 | CLEARINT1 | 0 | Clear compare interrupt 1. <i>Read:</i> Interrupt is disabled. <i>Write:</i> Corresponding bit is unchanged. |
| | | 1 | <i>Read:</i> Interrupt is enabled. <i>Write:</i> Interrupt is disabled. |
| 0 | CLEARINT0 | 0 | Clear compare interrupt 0. <i>Read:</i> Interrupt is disabled. <i>Write:</i> Corresponding bit is unchanged. |
| | | 1 | <i>Read:</i> Interrupt is enabled. <i>Write:</i> Interrupt is disabled. |

13.3.27 RTI Interrupt Flag Register (RTIINTFLAG)

The corresponding flags are set at every compare match of the RTIFRCx and RTICOMPx values, whether the interrupt is enabled or not. This register is shown in [Figure 13-38](#) and described in [Table 13-28](#).

Figure 13-38. RTI Interrupt Flag Register (RTIINTFLAG) [offset = 88h]

| | | | | | |
|----------|--|----|-----------|-----------|-----------|
| 31 | | 19 | 18 | 17 | 16 |
| Reserved | | | OVL1INT | OVL0INT | TBINT |
| R-0 | | | R/W1CP-0 | R/W1CP-0 | R/W1C P-0 |
| 15 | | 4 | 3 | 2 | 1 |
| Reserved | | | INT3 | INT2 | INT1 |
| R-0 | | | R/W1C P-0 | R/W1C P-0 | R/W1C P-0 |

LEGEND: R/W = Read/Write; R = Read only; W1CP = Write 1 to clear in privilege mode only; -n = value after reset

Table 13-28. RTI Interrupt Flag Register (RTIINTFLAG) Field Descriptions

| Bit | Field | Value | Description |
|-------|----------|-------|--|
| 31-19 | Reserved | 0 | Reads return 0. Writes have no effect. |
| 18 | OVL1INT | 0 | Free running counter 1 overflow interrupt flag. This bit determines if an interrupt is pending. <i>Read:</i> No interrupt is pending. <i>Write:</i> Bit is unchanged. |
| | | 1 | <i>Read:</i> Interrupt is pending. <i>Write:</i> Bit is cleared to 0. |
| 17 | OVL0INT | 0 | Free running counter 0 overflow interrupt flag. This bit determines if an interrupt is pending. <i>Read:</i> No interrupt is pending. <i>Write:</i> Bit is unchanged. |
| | | 1 | <i>Read:</i> Interrupt is pending. <i>Write:</i> Bit is cleared to 0. |
| 16 | TBINT | 0 | Timebase interrupt flag. This flag is set when the TBEXT bit is cleared by detection of a missing external clock edge. It will not be set by clearing TBEXT by software. It determines if an interrupt is pending. <i>Read:</i> No interrupt is pending. <i>Write:</i> Bit is unchanged. |
| | | 1 | <i>Read:</i> Interrupt is pending. <i>Write:</i> Bit is cleared to 0. |
| 15-4 | Reserved | 0 | Reads return 0. Writes have no effect. |
| 3 | INT3 | 0 | Interrupt flag 3. These bits determine if an interrupt due to a Compare 3 match is pending. <i>Read:</i> No interrupt is pending. <i>Write:</i> Bit is unchanged. |
| | | 1 | <i>Read:</i> Interrupt is pending. <i>Write:</i> Bit is cleared to 0. |
| 2 | INT2 | 0 | Interrupt flag 2. These bits determine if an interrupt due to a Compare 2 match is pending. <i>Read:</i> No interrupt is pending. <i>Write:</i> Bit is unchanged. |
| | | 1 | <i>Read:</i> Interrupt is pending. <i>Write:</i> Bit is cleared to 0. |
| 1 | INT1 | 0 | Interrupt flag 1. These bits determine if an interrupt due to a Compare 1 match is pending. <i>Read:</i> No interrupt is pending. <i>Write:</i> Bit is unchanged. |
| | | 1 | <i>Read:</i> Interrupt is pending. <i>Write:</i> Bit is cleared to 0. |

Table 13-28. RTI Interrupt Flag Register (RTIINTFLAG) Field Descriptions (continued)

| Bit | Field | Value | Description |
|-----|-------|-------|---|
| 0 | INT0 | 0 | Interrupt flag 0. These bits determine if an interrupt due to a Compare 0 match is pending. <i>Read:</i> No interrupt is pending. <i>Write:</i> Bit is unchanged. |
| | | 1 | <i>Read:</i> Interrupt is pending. <i>Write:</i> Bit is cleared to 0. |

13.3.28 Digital Watchdog Control Register (RTIDWDCTRL)

The software has to write to the DWDCTRL field in order to enable the DWD, as described below. Once enabled, the watchdog can only be disabled by a system reset. The application cannot disable the watchdog. However should the RTICLK source be changed to a source that is unimplemented it will have the same effect as disabling the watchdog. This register is shown in [Figure 13-38](#) and described in [Table 13-28](#).

Figure 13-39. Digital Watchdog Control Register (RTIDWDCTRL) [offset = 90h]

| | | | |
|------------|--|--|----|
| 31 | | | 16 |
| DWDCTRL | | | |
| R/WP-5312h | | | |
| 15 | | | 0 |
| DWDCTRL | | | |
| R/WP-ACEDh | | | |

LEGEND: R/W = Read/Write; R = Read only; WP = Write in privileged mode only; -n = value after reset

Table 13-29. Digital Watchdog Control Register (RTIDWDCTRL) Field Descriptions

| Bit | Field | Value | Description |
|------|---------|------------------|---|
| 31-0 | DWDCTRL | 5312 ACEDh | Digital Watchdog Control. <i>Read:</i> DWD counter is disabled. <i>Write:</i> State of DWD counter is unchanged (stays enabled or disabled). |
| | | A985 59DAh | <i>Read:</i> DWD counter is enabled. <i>Write:</i> DWD counter is enabled. |
| | | All other values | <i>Read:</i> DWD counter state is unchanged (enabled or disabled). <i>Write:</i> State of DWD counter is unchanged (stays enabled or disabled). Note: Once the enable value is written, all other future writes are blocked. In other words, once DWD is enabled, it can only be disabled by system reset or power on reset. However should the RTICLK source be changed to a source that is unimplemented it will have the same effect as disabling the watchdog. |

13.3.29 Digital Watchdog Preload Register (RTIDWDPRLD)

This register sets the expiration time of the DWD. This register is shown in [Figure 13-38](#) and described in [Table 13-28](#).

Figure 13-40. Digital Watchdog Preload Register (RTIDWDPRLD) [offset = 94h]

LEGEND: R/W = Read/Write; R = Read only; WP = Write in privileged mode only; -n = value after reset

Table 13-30. Digital Watchdog Preload Register (RTIDWDPRLD) Field Descriptions

| Bit | Field | Value | Description |
|-------|----------|--------|--|
| 31-12 | Reserved | 0 | Reads return 0 and writes have no effect. |
| 11-0 | DWDPRLD | 0-FFFh | Digital Watchdog Preload Value. <i>Read:</i> The current preload value <i>Write:</i> Set the preload value. The DWD preload register can be configured only when the DWD is disabled. Therefore, the application can only configure the DWD preload register before it enables the DWD down counter. The expiration time of the DWD Down Counter can be determined with following equation: $texp = (DWDPRLD + 1) \times 2^{13} / RTICLK1$ where: DWDPRLD = 0...4095 |

13.3.30 Watchdog Status Register (RTIWDSTATUS)

This register records the status of the DWD. The values of the following status bits will not be affected by a soft reset. These bits are cleared by a power up reset, or by a write of '1'. These bits can be used for debug purposes. This register is shown in [Figure 13-38](#) and described in [Table 13-28](#).

Figure 13-41. Watchdog Status Register (RTIWDSTATUS) [offset = 98h]

| | | | | | | | |
|----------|---|----------|---------------|-----------------|----------|----------|----------|
| 31 | | | | | | | 8 |
| Reserved | | | | | | | |
| R-0 | | | | | | | |
| 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| Reserved | | DWWD ST | END TIME VIOL | START TIME VIOL | KEY ST | DWD ST | Reserved |
| R-0 | | R/W1CP-x | R/W1CP-x | R/W1CP-x | R/W1CP-x | R/W1CP-x | R-0 |

LEGEND: R/W = Read/Write; R = Read only; W1CP = Write 1 to clear in privilege mode only; -n = value after reset

Table 13-31. Watchdog Status Register (RTIWDSTATUS) Field Descriptions

| Bit | Field | Value | Description |
|------|-----------------|-------|---|
| 31-6 | Reserved | 0 | Reads return 0. Writes have no effect. |
| 5 | DWWD ST | 0 | Windowed Watchdog Status <i>Read:</i> No time-window violation has occurred. <i>Write:</i> Leaves the current value unchanged. |
| | | 1 | <i>Read:</i> Time-window violation has occurred. The watchdog has generated either a system reset or a non-maskable interrupt to the CPU in this case. <i>Write:</i> Bit is cleared to 0. This will also clear all other status flags in the RTIWDSTATUS register. Clearing of the status flags will deassert the non-maskable interrupt generated due to violation of the DWWD. |
| 4 | END TIME VIOL | 0 | Windowed Watchdog End Time Violation Status. This bit indicates whether the Watchdog counter expired. <i>Read:</i> No end-time window violation has occurred. <i>Write:</i> Leaves the current value unchanged. |
| | | 1 | <i>Read:</i> End-time defined by the windowed watchdog configuration has been violated. <i>Write:</i> Bit is cleared to 0. |
| 3 | START TIME VIOL | 0 | Windowed Watchdog Start Time Violation Status. This bit indicates whether the key is written before the watchdog window opened up. <i>Read:</i> No start-time window violation has occurred. <i>Write:</i> Leaves the current value unchanged. |
| | | 1 | <i>Read:</i> Start-time defined by the windowed watchdog configuration has been violated. <i>Write:</i> Bit is cleared to 0. |
| 2 | KEY ST | 0 | Watchdog key status. This bit indicates a reset or NMI generated by a wrong key or key sequence written to the RTIWDKEY register. <i>Read:</i> No wrong key or key-sequence written. <i>Write:</i> Bit is unchanged. |
| | | 1 | <i>Read:</i> Wrong key or key-sequence written to RTIWDKEY register. <i>Write:</i> Bit is cleared to 0. |
| 1 | DWD ST | 0 | DWD status. This bit is equivalent to bit END TIME VIOL. <i>Read:</i> No reset or NMI was generated. <i>Write:</i> Bit is unchanged. |
| | | 1 | <i>Read:</i> Reset or NMI was generated. <i>Write:</i> Bit is cleared to 0. |
| 0 | Reserved | 0 | Reads return 0. Writes have no effect. |

13.3.31 RTI Watchdog Key Register (RTIWDKEY)

This register must be written with the correct written key values to serve the watchdog. This register is shown in [Figure 13-42](#) and described in [Table 13-32](#).

NOTE: It has to be taken into account that the write to the RTIWDKEY register takes 3 VCLK cycles.

Figure 13-42. RTI Watchdog Key Register (RTIDWDKEY) [offset = 9Ch]

LEGEND: R/W = Read/Write; R = Read only; WP = Write in privileged mode only; -n = value after reset

Table 13-32. RTI Watchdog Key Register (RTIDWDKEY) Field Descriptions

| Bit | Field | Value | Description |
|-------|----------|---------|--|
| 31-16 | Reserved | 0 | Reads return 0 and writes have no effect. |
| 15-0 | WDKEY | 0-FFFFh | Watchdog key. These bits provide the key sequence location. Reads returns the current WDKEY value. A write of E51Ah followed by A35Ch in two separate write operations defines the key sequence and reloads the DWD. Writing any other value causes a reset or NMI, as shown in Table 13-33 . Writing any other value will cause the WDKEY to reset to A35Ch. |

Table 13-33. Example of a WDKEY Sequence

| Step | Value Written to WDKEY | Result |
|------|------------------------|--|
| 1 | A35Ch | No action |
| 2 | A35Ch | No action |
| 3 | E51Ah | WDKEY is enabled for reset or NMI by next A35Ch. |
| 4 | E51Ah | WDKEY is enabled for reset or NMI by next A35Ch. |
| 5 | E51Ah | WDKEY is enabled for reset or NMI by next A35Ch. |
| 6 | A35Ch | Watchdog is reset. |
| 7 | A35Ch | No action |
| 8 | E51Ah | WDKEY is enabled for reset or NMI by next A35Ch. |
| 9 | A35Ch | Watchdog is reset. |
| 10 | E51Ah | WDKEY is enabled for reset or NMI by next A35Ch. |
| 11 | 2345h | System reset or NMI; incorrect value written to WDKEY. |

13.3.32 RTI Digital Watchdog Down Counter (RTIDWDCNTR)

This register provides the current value of the DWD down counter. This register is shown in [Figure 13-43](#) and described in [Table 13-34](#).

Figure 13-43. RTI Watchdog Down Counter Register (RTIDWDCNTR) [offset = A0h]

| | | | |
|----------|----|--------|----|
| 31 | 25 | 24 | 16 |
| Reserved | | DWDNTR | |
| R-0 | | R-1FFh | |
| 15 | | | 0 |
| DWDNTR | | | |
| R-FFFFh | | | |

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 13-34. RTI Watchdog Down Counter Register (RTIDWDCNTR) Field Descriptions

| Bit | Field | Value | Description |
|-------|----------|-------------|--|
| 31-25 | Reserved | 0 | Reads return 0 and writes have no effect. |
| 24-0 | DWDNTR | 0-1FF FFFFh | DWD down counter. Reads return the current counter value. |

13.3.33 Digital Windowed Watchdog Reaction Control (RTIWWDRXNCTRL)

This register selects the DWWD reaction if the watchdog is serviced outside the time window. This register is shown in [Figure 13-44](#) and described in [Table 13-35](#).

Figure 13-44. Digital Windowed Watchdog Reaction Control (RTIWWDRXNCTRL) [offset = A4h]

| | | | | | | |
|----------|--|--|--|---------|---|---|
| 31 | | | | 16 | | |
| Reserved | | | | | | |
| R-0 | | | | | | |
| 15 | | | | 4 | 3 | 0 |
| Reserved | | | | WWDRXN | | |
| R-0 | | | | R/WP-5h | | |

LEGEND: R/W = Read/Write; R = Read only; WP = Write in privileged mode only; -n = value after reset

Table 13-35. Digital Windowed Watchdog Reaction Control (RTIWWDRXNCTRL) Field Descriptions

| Bit | Field | Value | Description |
|------|----------|------------------|---|
| 31-4 | Reserved | 0 | Reads return 0 and writes have no effect. |
| 3-0 | WWDRXN | 5h | The windowed watchdog will cause a reset if the watchdog is serviced outside the time window defined by the configuration, or if the watchdog is not serviced at all. |
| | | Ah | The windowed watchdog will generate a non-maskable interrupt to the CPU if the watchdog is serviced outside the time window defined by the configuration, or if the watchdog is not serviced at all. |
| | | All other values | The windowed watchdog will cause a reset if the watchdog is serviced outside the time window defined by the configuration, or if the watchdog is not serviced at all. Note: The DWWD reaction can be selected by the application even when the DWWD counter is already enabled. If a change to the WWDRXN is made before the watchdog service window is opened, then the change in the configuration takes effect immediately. If a change to the WWDRXN is made when the watchdog service window is already open, then the change in configuration takes effect only after the watchdog is serviced. |

13.3.34 Digital Windowed Watchdog Window Size Control (RTIWWDSIZECTRL)

This register selects the DWWD window size. This register is shown in [Figure 13-45](#) and described in [Table 13-36](#).

Figure 13-45. Digital Windowed Watchdog Window Size Control (RTIWWDSIZECTRL) [offset = A8h]

LEGEND: R/W = Read/Write; R = Read only; WP = Write in privileged mode only; -n = value after reset

**Table 13-36. Digital Windowed Watchdog Window Size Control (RTIWWDSIZECTRL)
Field Descriptions**

| Bit | Field | Value | Description |
|------|---------|------------------|---|
| 31-0 | WWDSIZE | 0 | The DWWD window size |
| | | 0000 0005h | 100% (The functionality is the same as the standard time-out digital watchdog.) |
| | | 0000 0050h | 50% |
| | | 0000 0500h | 25% |
| | | 0000 5000h | 12.5% |
| | | 0005 0000h | 6.25% |
| | | All other values | 3.125% |
| | | | Note: The DWWD window size can be selected by the application even when the DWWD counter is already enabled. If a change to the WWDSIZE is made before the watchdog service window is opened, then the change in the configuration takes effect immediately. If a change to the WWDSIZE is made when the watchdog service window is already open, then the change in configuration takes effect only after the watchdog is serviced. |

13.3.35 RTI Compare Interrupt Clear Enable Register (RTIINTCLREnable)

When the RTI compare event is configured to generate a DMA request or triggers (all triggered by RTI compare interrupt request flag) to other peripherals, it is often desirable to clear the RTI compare flag automatically so that the requests can be generated repeatedly without any CPU intervention. This register works with the RTI compare clear registers to enable an "auto-clear" of the compare interrupt enable bit after a compare equal event. This register is shown in [Figure 13-46](#) and described in [Table 13-37](#).

13.3.36 RTI Compare 0 Clear Register (RTICMP0CLR)

This registers holds an initial value which is larger than the value in the RTI Compare 0 register [Section 13.3.4](#). The user needs to choose the value such that the compare clear 0 event occurs before next compare 0 event. If the Free Running Counter matches the compare value, the compare 0 interrupt request flag is cleared and the value in the RTIUDCP0 register [Section 13.3.16](#) is added to this register. This register is shown in [Figure 13-47](#) and described in [Table 13-38](#).

Cyclic Redundancy Check (CRC) Controller Module

This chapter describes the cyclic redundancy check (CRC) controller module.

NOTE: This chapter describes a superset implementation of the CRC module that includes features and functionality that require DMA. Since not all devices have DMA capability, consult your device-specific datasheet to determine applicability of these features and functions to your device being used.

| Topic | Page |
|---|------------|
| 14.1 Overview | 489 |
| 14.2 Module Operation | 491 |
| 14.3 Example | 502 |
| 14.4 CRC Control Registers | 505 |

14.1 Overview

The CRC controller is a module that is used to perform CRC (Cyclic Redundancy Check) to verify the integrity of memory system. A signature representing the contents of the memory is obtained when the contents of the memory are read into CRC controller. The responsibility of CRC controller is to calculate the signature for a set of data and then compare the calculated signature value against a pre-determined good signature value. CRC controller supports two channels to perform CRC calculation on multiple memories in parallel and can be used on any memory system.

14.1.1 Features

The CRC controller offers:

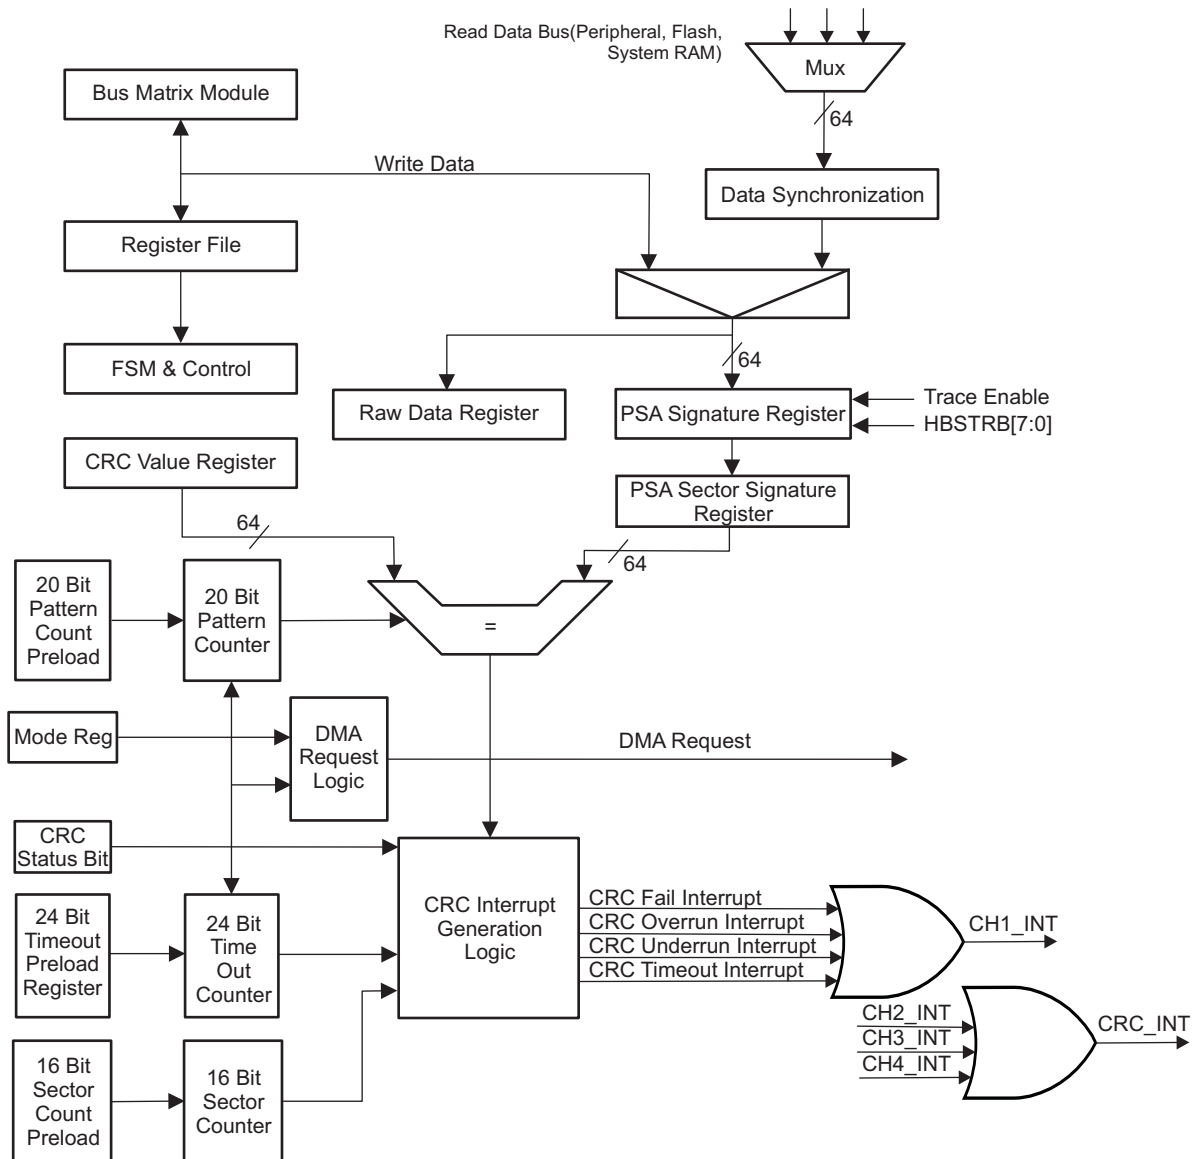

- Two channels to perform background signature verification on any memory sub-system.
- Data compression on 8, 16, 32, and 64 bit data size.
- Maximum-length PSA (Parallel Signature Analysis) register constructed based on 64 bit primitive polynomial.
- Each channel has a CRC Value Register that contains the pre-determined CRC value.
- Use timed base event trigger from timer to initiate DMA data transfer.
- Programmable 20-bit pattern counter per channel to count the number of data patterns for compression.
- Three modes of operation: Auto, Semi-CPU, and Full-CPU.
- For each channel, CRC can be performed either by CRC Controller or by CPU.
- Automatically perform signature verification without CPU intervention in AUTO mode.
- Generate interrupt to CPU in Semi-CPU mode to allow CPU to perform signature verification itself.
- Generate CRC fail interrupt in AUTO mode if signature verification fails.
- Generate Timeout interrupt if CRC is not performed within the time limit.
- Generate DMA request per channel to initiate CRC value transfer.
- Data trace capability on Peripheral Bus Master, Flash and System RAM data buses.

14.1.2 Block Diagram

Figure 14-1 shows a block diagram of the CRC controller.

NOTE: Only Channel 1 can support data trace. See [Section 14.2.11](#).

Figure 14-1. CRC Controller Block Diagram For One Channel

14.2 Module Operation

14.2.1 General Operation

There are two channels in CRC controller and for each channel there is a memory-mapped PSA (Parallel Signature Analysis) Signature Register and a memory-mapped CRC (Cyclic Redundancy Check) Value register. A memory can be organized into multiple sectors with each sector consisting of multiple data patterns. A data pattern can be a 8, 16, 32, or 64 bit data. CRC module performs the signature calculation and compares the signature to a pre-determined value. The PSA Signature Register compresses an incoming data pattern into a signature when it is written. When one sector of data patterns are written into PSA Signature Register, a final signature corresponding to the sector is obtained. CRC Value Register stores the pre-determined signature corresponding to one sector of data patterns. The calculated signature and the pre-determined signature are then compared to each other for signature verification. To minimize CPU's involvement, data patterns transfer can be carried out at the background of CPU using DMA controller. DMA is setup to transfer data from memory from which the contents to be verified to the memory-mapped PSA Signature Register. When DMA transfers data to the memory-mapped PSA Signature Register, a signature is generated. A programmable 20-bit data pattern counter is used for each channel to define the number of data patterns to calculate for each sector. Signature verification can be performed automatically by CRC controller in AUTO mode or by CPU itself in Semi-CPU or Full-CPU mode. In AUTO mode, a self sustained CRC signature calculation can be achieved without any CPU intervention. CRC Controller also provides data trace capability. Channel 1 can perform data trace on CPU data bus. During data trace, channel 1 monitors any data being read on CPU data bus and compresses it. When data trace is enabled for channel 1, all circuits related to DMA request and interrupt generation and counters are disabled.

14.2.2 CRC Modes of Operation

CRC Controller can operate in AUTO, Semi-CPU, and Full-CPU modes.

14.2.2.1 AUTO Mode

In AUTO mode, CRC Controller in conjunction with DMA controller can perform CRC totally without CPU intervention. A sustained transfer of data to both the PSA Signature Register and CRC Value Register are performed in the background of CPU. When a mismatch is detected, an interrupt is generated to CPU. A 16 bit current sector ID register is provided to identify which sector causes a CRC failure.

14.2.2.2 Semi-CPU Mode

In Semi-CPU mode, DMA controller is also utilized to perform data patterns transfer to PSA Signature Register. Instead of performing signature verification automatically, the CRC controller generates an compression complete interrupt to CPU after each sector is compressed. Upon responding to the interrupt the CPU performs the signature verification by reading the calculated signature stored at the PSA Sector Signature Register and compare it to a pre-determined CRC value.

14.2.2.3 Full CPU Mode

In Full-CPU mode, the CPU does the data patterns transfer and signature verification all by itself. When CPU has enough throughput, it can perform data patterns transfer by reading data from the memory system to the PSA Signature Register. After certain number of data patterns are compressed, the CPU can read from the PSA Signature Register and compare the calculated signature to the pre-determined CRC signature value. In Full-CPU mode, neither interrupt nor DMA request is generated. All counters are also disabled.

14.2.3 PSA Signature Register

The 64-bit PSA Signature Register is based on the primitive polynomial (as in the following equation) to produce the maximum length LFSR (Linear Feedback Shift Register), as shown in [Figure 14-2](#).

$$f(x) = x^{64} + x^4 + x^3 + x + 1 \quad (26)$$

Figure 14-2. LFSR

The serial implementation of LFSF has a limitation that, it requires 'n' clock cycles to calculate the CRC values for an 'n' bit data stream. The idea is to produce the same CRC value operating on a multi-bit data stream, as would occur if the CRC were computed one bit at a time over the whole data stream. The algorithm involves looping to simulate the shifting, and concatenating strings to build the equations after 'n' shift.

The parallel CRC calculation based on the polynomial can be illustrated in the following HDL code:

```
for i in 63 to 0 loop
  NEXT_CRC_VAL(0) := CRC_VAL(63) xor DATA(i);
  for j in 1 to 63 loop
    case j is
      when 1|3|4 =>
        NEXT_CRC_VAL(j) :=
          CRC_VAL(j - 1) xor CRC_VAL(63) xor DATA(i);
      when others =>
        NEXT_CRC_VAL(j) := CRC_VAL(j - 1);
    end case;
  end loop;
  CRC_VAL := NEXT_CRC_VAL;
end loop;
```

- NOTE:**
- 1) The inner loop is to calculate the next value of each shift register bit after one cycle
 - 2) The outer loop is to simulate 64 cycles of shifting. The equation for each shift register bit is thus built before it is compressed into the shift register.
 - 3) MSB of the DATA is shifted in first

There is one PSA Signature Register per CRC channel. PSA Signature Register can be both read and written. When it is written, it can either compress the data or just capture the data depending on the state of CHx_MODE bits. If CHx_MODE=Data Capture, a seed value can be planted in the PSA Signature Register without compression. Other modes other than Data Capture will result with the data compressed by PSA Signature Register when it is written. Each channel can be planted with different seed value before compression starts. When PSA Signature Register is read, it gives the calculated signature.

CRC Controller should be used in conjunction with the on chip DMA controller to produce optimal system performance. The incoming data pattern to PSA Signature Register is typically initiated by the DMA master. When DMA is properly setup, it would read data from the pre-determined memory system and write them to the memory-mapped PSA Signature Register. Each time PSA Signature Register is written a signature is generated. CPU itself can also perform data transfer by reading from the memory system and perform write operation to PSA Signature Register if CPU has enough throughput to handle data patterns transfer.

After system reset and when AUTO mode is enabled, CRC Controller automatically generates a DMA request to request the pre-determined CRC value corresponding to the first sector of memory to be checked.

In AUTO mode, when one sector of data patterns is compressed, the signature stored at the PSA Signature Register is first copied to the PSA Sector Signature Register and PSA Signature Register is then cleared out to all zeros. An automatic signature verification is then performed by comparing the signature stored at the PSA Sector Signature Register to the CRC Value Register. After the comparison the CRC Controller can generate a DMA request. Upon receiving the DMA request the DMA controller will update the CRC Value Register by transferring the next pre-determined signature value associated with the next sector of memory system. If the signature verification fails then CRC Controller can generate a CRC fail interrupt.

In Full-CPU mode, no DMA request and interrupt are generated at all. The number of data patterns to be compressed is determined by CPU itself. Full-CPU mode is useful when DMA controller is not available to perform background data patterns transfer. The OS can periodically generate a software interrupt to CPU and use CPU to accomplish data transfer and signature verification.

CRC Controller supports doubleword, word, half word and byte access to the PSA Signature Register. During a non-doubleword write access, all unwritten byte lanes are padded with zero's before compression. Note that comparison between PSA Sector Signature Register and CRC Value Register is always in 64 bit because a compressed value is always expressed in 64 bit.

There is a software reset per channel for PSA Signature Register. When set, the PSA Signature Register is reset to all zeros.

PSA Signature Register is reset to zero under the following conditions:

- System reset
- PSA Software reset
- One sector of data patterns are compressed

14.2.4 PSA Sector Signature Register

After one sector of data is compressed, the final resulting signature calculated by PSA Signature Register is transferred to the PSA Sector Signature Register. PSA Signature Register is a read only register. During Semi-CPU mode, the host CPU should read from the PSA Sector Signature Register instead of reading from PSA Signature Register for signature verification to avoid data coherency issue. The PSA Signature Register can be updated with new signature before the host CPU is able to retrieve it.

In Semi-CPU mode, no DMA request is generated. When one sector of data patterns is compressed, CRC controller first generates a compression complete interrupt. Responding to the interrupt, CPU will in the ISR read the PSA Sector Signature Register and compare it to the known good signature or write the signature value to another memory location to build a signature file. In Semi-CPU mode, CPU must perform the signature verification in a manner to prevent any overrun condition. The overrun condition occurs when the compression complete interrupt is generated after one sector of data patterns is compressed and CPU has not read from the PSA Sector Signature Register to perform necessary signature verification before PSA Sector Signature Register is overridden with a new value. An overrun interrupt can be enable to generate when overrun condition occurs. During Semi-CPU mode, the host CPU should read from the PSA Sector Signature Register instead of reading from PSA Signature Register for signature verification to avoid data coherency issue. The PSA Signature Register can be updated with new signature before the host CPU is able to retrieve it.

14.2.5 CRC Value Register

Associated with each channel there is a CRC Value Register. The CRC Value Register stores the pre-determined CRC value. After one sector of data patterns is compressed by PSA Signature Register, CRC Controller can automatically compare the resulting signature stored at the PSA Sector Signature Register with the pre-determined value stored at the CRC Value Register if AUTO mode is enabled. If the signature verification fails, CRC Controller can be enabled to generate an CRC fail interrupt. When the channel is set up for Semi-CPU mode, CRC controller first generates a compression complete interrupt to CPU. Upon servicing the interrupt, CPU will then read the PSA Sector Signature Register and then read the corresponding CRC value stored at another location and compare them. CPU should not read from the CRC Value Register during Semi-CPU or Full-CPU mode because the CRC Value Register is not updated during these two modes.

In AUTO mode, for first sector's signature, DMA request is generated when mode is programmed to AUTO. For subsequent sectors, DMA request is generated after each sector is compressed. Responding to the DMA request, DMA controller reloads the CRC Value Register for the next sector of memory system to be checked.

When CRC Value Register is updated with a new CRC value, an internal flag is set to indicate that CRC Value Register contains the most current value. This flag is cleared when CRC comparison is performed. Each time at the end of the final data pattern compression of a sector, CRC Controller first checks to see if the corresponding CRC Value Register has the most current CRC value stored in it by polling the flag. If the flag is set then the CRC comparison can be performed. If the flag is not set then it means the CRC Value Register contains stale information. A CRC underrun interrupt is generated. When an underrun condition is detected, signature verification is not performed.

CRC Controller supports doubleword, word, half word and byte access to the CRC Value Register. As noted before comparison between PSA Sector Signature Register and CRC Value Register during AUTO mode is carried out in 64 bit.

14.2.6 Raw Data Register

The raw or un-compressed data written to the PSA Signature Register is also saved in the Raw Data Register. This register is read only.

14.2.7 Example DMA Controller Setup

DMA controller needs to be setup properly in either AUTO or Semi-CPU mode as DMA controller is used to transfer data patterns. Hardware or a combination of hardware and software DMA triggering are supported.

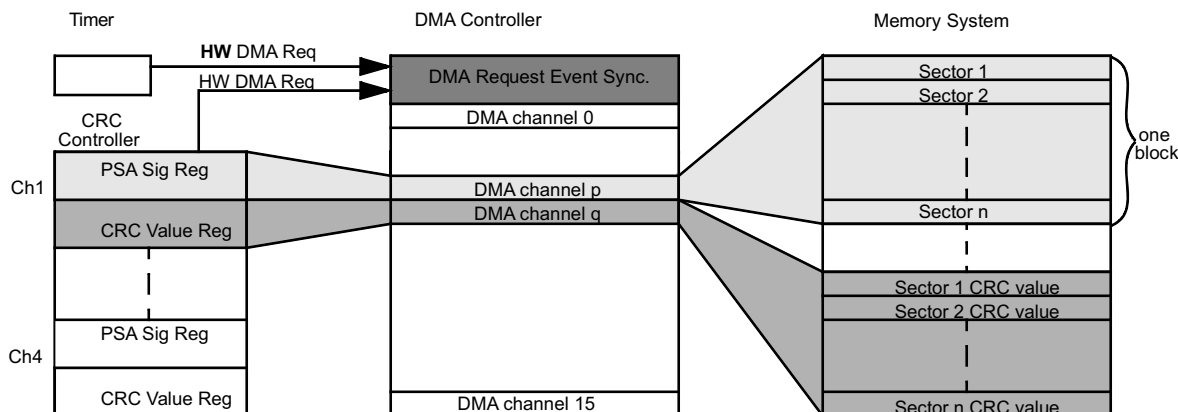

14.2.7.1 AUTO Mode Using Hardware Timer Trigger

There are two DMA channels associated with each CRC channel when in AUTO mode. One DMA channel is setup to transfer data patterns from the source memory to the PSA Signature Register. The second DMA channel is setup to transfer the pre-determined signature to the CRC Value Register. The trigger source for the first DMA channel can be either by hardware or by software. As illustrated in [Figure 14-3](#) a timer can be used to trigger a DMA request to initiate transfer from the source memory system to PSA Signature Register. In AUTO mode, CRC Controller also generates DMA request after one sector of data patterns is compressed to initiate transfer of the next CRC value corresponding to the next sector of memory. Thus a new CRC value is always updated in the CRC Value Register by DMA synchronized to each sector of memory.

A block of memory system is usually divided into many sectors. All sectors are the same size. The sector size is programmed in the CRC_PCOUNT_REGx and the number of sectors in one block is programmed in the CRC_SCOUNT_REGx of the respective channel. CRC_PCOUNT_REGx multiplies CRC_SCOUNT_REGx and multiplies transfer size of each data pattern should give the total block size in number of bytes.

The total size of the memory system to be examined is also programmed in the respective transfer count register inside DMA module. The DMA transfer count register is divided into two parts. They are element count and frame count. Note that an HW DMA request can be programmed to trigger either one frame or one entire block transfer. In [Figure 14-3](#), an HW DMA request from a timer is used as a trigger source to initiate DMA transfer. If all four CRC channels are active in AUTO mode then a total of four DMA requests would be generated by CRC Controller.

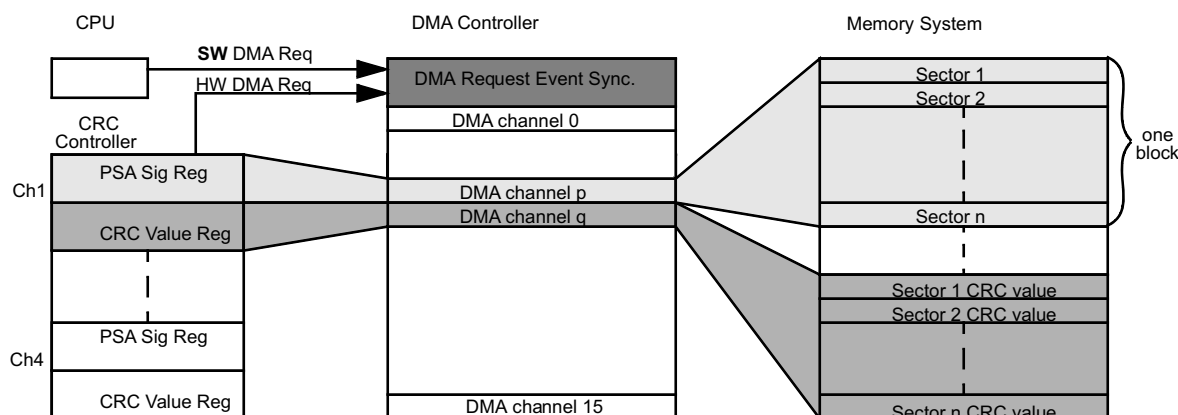

Figure 14-3. AUTO Mode Using Hardware Timer Trigger

14.2.7.2 AUTO Mode Using Software Trigger

The data patterns transfer can also be initiated by software. CPU can generate a software DMA request to activate the DMA channel to transfer data patterns from source memory system to the PSA Signature Register. To generate a software DMA request CPU needs to set the corresponding DMA channel in the DMA software trigger register. Note that just one software DMA request from CPU is enough to complete the entire data patterns transfer for all sectors. See [Figure 14-4](#) for an illustration.

Figure 14-4. AUTO Mode With Software CPU Trigger

14.2.7.3 Semi-CPU Mode Using Hardware Timer Trigger

During semi-CPU mode, no DMA request is generated by CRC controller. Therefore, no DMA channel is allocated to update CRC Value Register. CPU should not read from CRC Value Register in semi-CPU mode as it contains stale value. Note that no signature verification is performed at all during this mode. Similar to AUTO mode, either by hardware or by software DMA request can be used as a trigger for data patterns transfer. Figure 14-5 illustrates the DMA setup using semi-CPU mode with hardware timer trigger.

Figure 14-5. Semi-CPU Mode With Hardware Timer Trigger

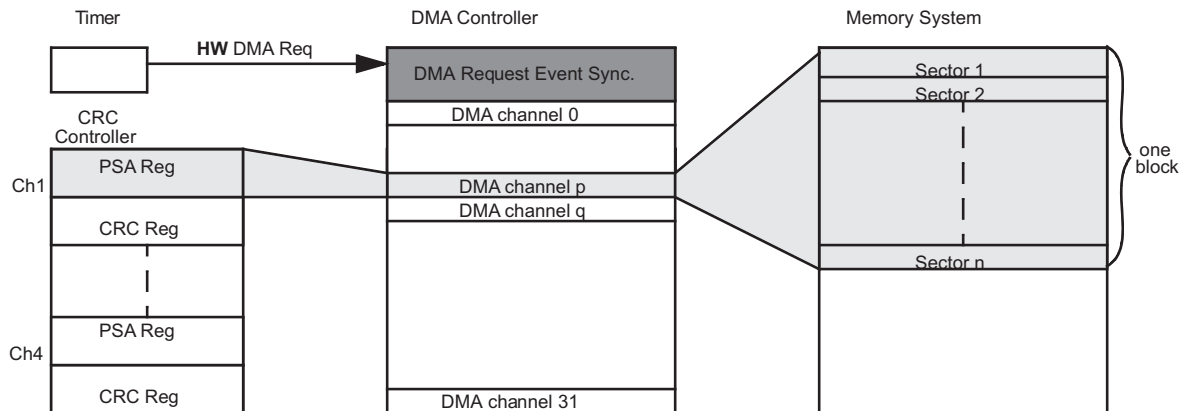

Table 14-1. CRC Modes in Which DMA Request and Counter Logic are Active or Inactive

| Mode | DMA Request | Pattern Counter | Sector Counter | Timeout Counter |
|----------|-------------|-----------------|----------------|-----------------|
| AUTO | Active | Active | Active | Active |
| Semi-CPU | Inactive | Active | Active | Active |
| Full-CPU | Inactive | Inactive | Inactive | Inactive |

14.2.8 Pattern Count Register

There is a 20-bit data pattern counter for every CRC channel. The data pattern counter is a down counter and can be pre-loaded with a programmable value stored in the Pattern Count Register. When the data pattern counter reaches zero, a compression complete interrupt is generated in Semi-CPU mode and an automatic signature verification is performed in AUTO mode. In AUTO only, DMA request is generated to trigger the DMA controller to update the CRC Value Register.

NOTE: The data pattern count should be divisible by the total transfer count as programmed in DMA controller. The total transfer count is the product of element count and frame count.

14.2.9 Sector Count Register/Current Sector Register

Each channel contains a 16 bit sector counter. The sector count register stores the number of sectors. Sector counter is a free running counter and is incremented by one each time when one sector of data patterns is compressed. When the signature verification fails, the current value stored in the sector counter is saved into current sector register. If signature verification fails, CPU can read from the current sector register to identify the sector which causes the CRC mismatch. To aid and facilitate the CPU in determining the cause of a CRC failure, it is advisable to use the following equation during CRC and DMA setup:

$$\text{CRC Pattern Count} \times \text{CRC Sector Count} = \text{DMA Element Count} \times \text{DMA Frame Count}$$

The current sector register is frozen from being updated until both the current sector register is read and CRC fail status bit is cleared by CPU. If CPU does not respond to the CRC failure in a timely manner before another sector produces a signature verification failure, the current sector register is not updated with the new sector number. An overrun interrupt is generate instead. If current sector register is already frozen with an erroneous sector and emulation is entered with SUSPEND signal goes to high then the register still remains frozen even it is read.

In Semi-CPU mode, the current sector register is used to indicate the sector for which the compression complete has last happened.

The current sector register is reset when the PSA software reset is enabled.

NOTE: Both data pattern count and sector count registers must be greater than or equal to one for the counters to count. After reset, pattern count and sector count registers default to zero and the associated counters are inactive.

14.2.10 Interrupt

The CRC controller generates several types of interrupts per channel. Associated with each interrupt, there is an interrupt enable bit. No interrupt is generated in Full-CPU mode.

- Compression complete interrupt
- CRC fail interrupt
- Overrun interrupt
- Underrun interrupt
- Timeout interrupt

Table 14-2. Modes in Which Interrupt Condition Can Occur

| | AUTO | Semi-CPU | Full-CPU |
|----------------------|-------------|-----------------|-----------------|
| Compression Complete | no | yes | no |
| CRC Fail | yes | no | no |
| Overrun | yes | yes | no |
| Underrun | yes | no | no |
| Timeout | yes | yes | no |

14.2.10.1 Compression Complete Interrupt

Compression complete interrupt is generated in Semi-CPU mode only. When the data pattern counter reaches zero, the compression complete flag is set and the interrupt is generated.

14.2.10.2 CRC Fail Interrupt

CRC fail interrupt is generated in AUTO mode only. When the signature verification fails, the CRC fail flag is set,. CPU should take action to address the fail condition and clear the CRC fail flag after it resolves the CRC mismatch.

14.2.10.3 Overrun Interrupt

Overrun interrupt is generated in either AUTO or Semi-CPU mode. During AUTO mode, if a CRC fail is detected, then the current sector number is recorded in the current sector register. If CRC fail status bit is not cleared and current sector register is not read by the host CPU before another CRC fail is detected for another sector, then an overrun interrupt is generated. During Semi-CPU mode, when the data pattern counter finishes counting, it generates a compression complete interrupt. At the same time, the signature is copied into the PSA Sector Signature Register. If the host CPU does not read the signature from PSA Sector Signature Register before it is updated again with a new signature value, then an overrun interrupt is generated.

14.2.10.4 Underrun Interrupt

Underrun interrupt only occurs in AUTO mode. The interrupt is generated when the CRC Value Register is not updated with the corresponding signature when the data pattern counter finishes counting. During AUTO mode, CRC Controller generates DMA request to update CRC Value Register in synchronization to the corresponding sector of the memory. Signature verification is also performed if underrun condition is detected. And CRC fail interrupt is generated at the same time as the underrun interrupt.

14.2.10.5 Timeout Interrupt

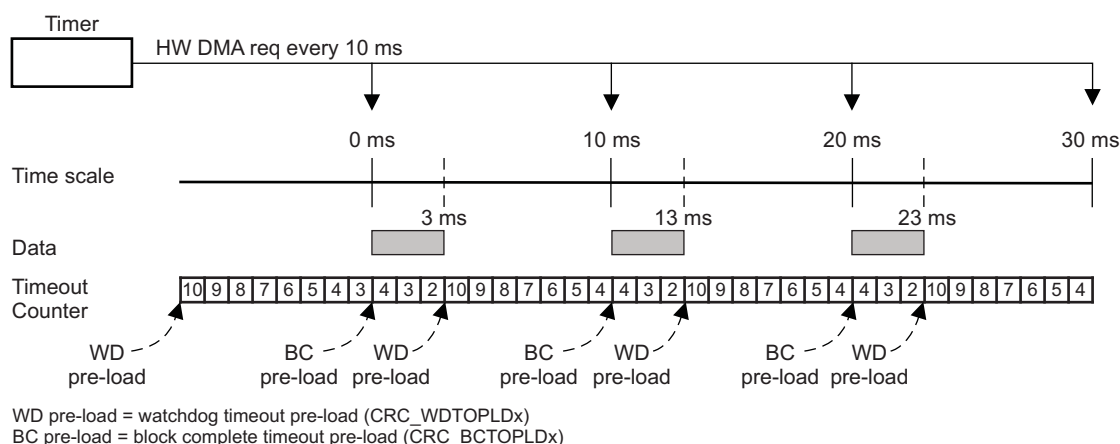

To ensure that the memory system is examined within a pre-defined time frame and no loss of incoming data there is a 24 bit timeout counter per CRC channel. The 24 bit timeout down counter can be pre-loaded with two different pre-load values, watchdog timeout pre-load value (CRC_WDTPLDx) and block complete timeout pre-load value (CRC_BCTOPLDx). The timeout counter is clocked by a prescaler clock which is permanently running at division 64 of HCLK clock.

First pattern of data must be transferred by the DMA before the timeout counter expires, Watchdog timeout pre-load register (CRC_WDTPLDx) is used as timeout counter. Block complete timeout pre-load register (CRC_BCTOPLDx) is used to check if one complete block of data patterns are compressed within a specific time frame. The timeout counter is first pre-loaded with CRC_WDTPLDx after either AUTO or Semi-CPU mode is selected and starts to down count. If the timeout counter expires before DMA transfers any data pattern to PSA Signature Register then a timeout interrupt is generated. An incoming data pattern before the timeout counter expires will automatically pre-load the timeout counter with CRC_BCTOPLDx the block complete timeout pre-load value.

Block complete timeout pre-load value is used to check if one block of data patterns are compressed within a given time limit. If the timeout counter pre-loaded with CRC_BCTOPLDx value expires before one block of data patterns are compressed a timeout interrupt is generated. When one block (pattern count x sector count) of data patterns are compressed before the counter has expired, the counter is pre-loaded with CRC_WDTPLDx value again. If the timeout counter is pre-loaded with zero then the counter is disable and no timeout interrupt is generated.

In [Figure 14-6](#), a timer generates DMA request every 10ms to trigger one block (pattern count x sector count) transfer. Since we want to make sure that DMA does start to transfer a block every 10 ms we would set the first pre-load value to 10ms in CRC_WDTPLDx. We also want to make sure that one block of data patterns are compressed within 4ms. With such a requirement, we would set the second pre-load value to 4ms in CRC_BCTOPLDx register.

Figure 14-6. Timeout Example 1

Note: No timeout interrupt is generated in this example since each block of data patterns are compressed in 3 ms and DMA does initiate a block transfer every 10 ms.

Figure 14-7. Timeout Example 2

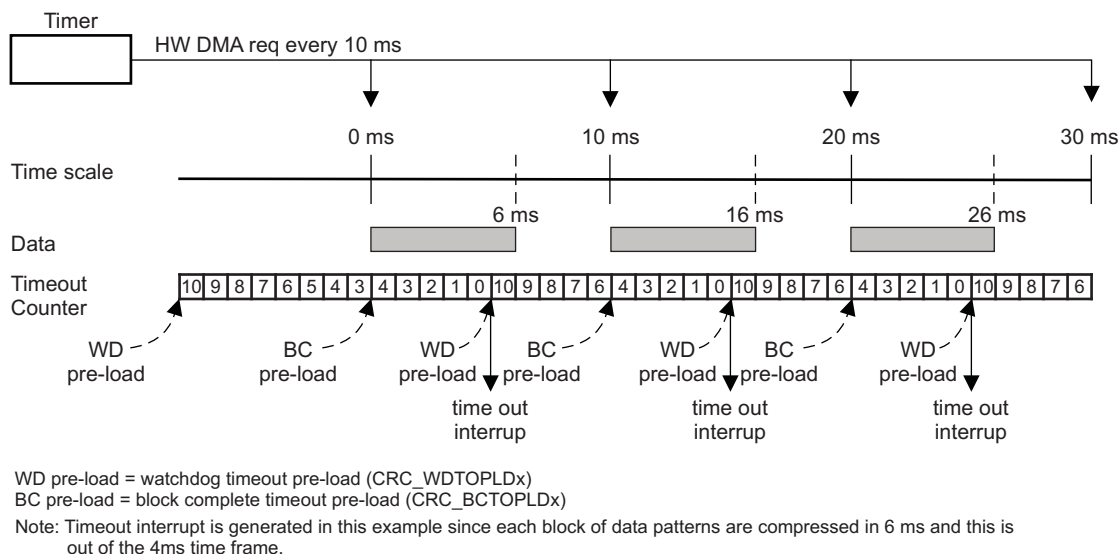

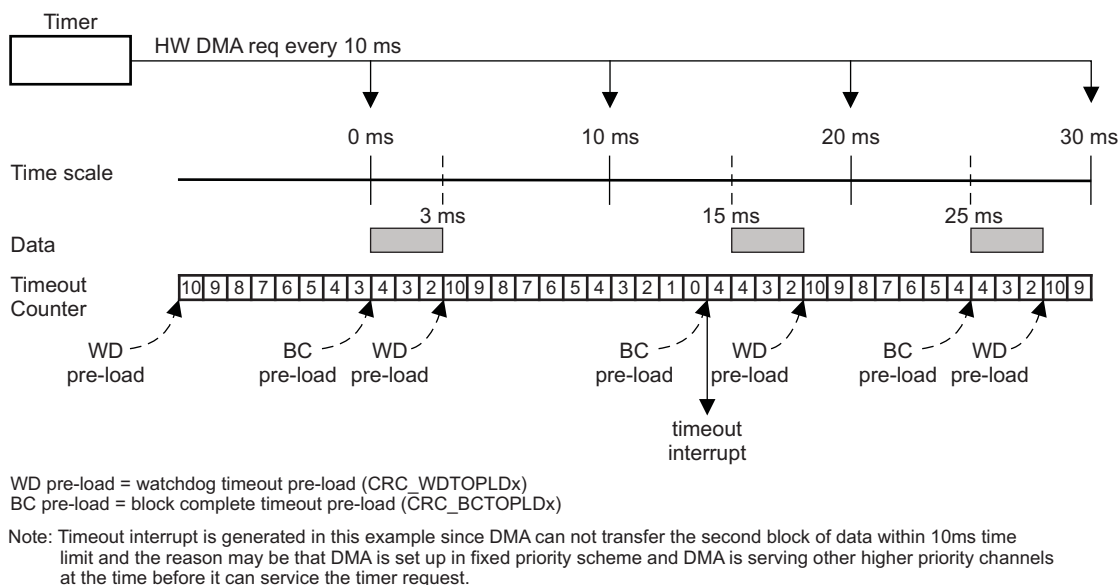

Figure 14-8. Timeout Example 3

14.2.10.6 Interrupt Offset Register

CRC Controller only generates one interrupt request to interrupt manager. A interrupt offset register is provided to indicate the source of the pending interrupt with highest priority. [Table 14-3](#) shows the offset interrupt vector address of each interrupt condition in an ascending order of priority.

Table 14-3. Interrupt Offset Mapping

| Offset Value | Interrupt Condition |
|--------------|--------------------------|
| 0 | Phantom |
| 1h | Ch1 CRC Fail |
| 2h | Ch2 CRC Fail |
| 3h-8h | Reserved |
| 9h | Ch1 Compression Complete |
| Ah | Ch2 Compression Complete |
| Bh-10h | Reserved |
| 11h | Ch1 Overrun |
| 12h | Ch2 Overrun |
| 13h-18h | Reserved |
| 19h | Ch1 Underrun |
| 1Ah | Ch2 Underrun |
| 1Bh-20h | Reserved |
| 21h | Ch1 Timeout |
| 22h | Ch2 Timeout |
| 23h-24h | Reserved |

14.2.10.7 Error Handling

When an interrupt is generated, host CPU should take appropriate actions to identify the source of error and restart the respective channel in DMA and CRC module. To restart a CRC channel, the user should perform the following steps in the ISR:

1. Write to software reset bit in CRC_CTRL register to reset the respective PSA Signature Register.
2. Reset the CHx_MODE bits to 00 in CRC_CTRL register as Data capture mode.
3. Set the CHx_MODE bits in CRC_CTRL register to desired new mode again.
4. Release software reset.

The host CPU should use byte write to restart each individual channel.

14.2.11 CPU Data Trace

CRC channel 1 can be used to snoop Flash, System RAM and Peripheral Bus Master Data buses. However, at any one point only one bus is snooped. It is possible to disable the snooping of any of the buses by programming CRC_BUS_SEL register. While snooping the data, there is a priority scheme implemented between the buses. Peripheral Bus Master has the highest priority followed by Flash, Even System RAM and Odd System RAM. For each data read by CPU on its data bus the same data is compressed in the PSA Signature Register. A write to PSA Signature Register does not get compressed. Therefore, it is possible to write a seed value into PSA Signature Register before the bus snooping takes place. During data trace mode, all interrupts and DMA request logic are inactive. For non double word read on the data bus, all un-selected byte lanes are padded with zero during compression.

14.2.11.1 Data Capture Mode used in Conjunction with Data Trace

Data capture mode is especially useful when it is used in conjunction when data trace for channel 1 is enabled (CRC_CTRL2.CH1_TRACEEN = 1). The seed value can be planted in PSA Signature Register during data capture mode by writing a seed value into PSA Signature Register. The data trace enable bit is then set to snoop and compress any read transaction on DAHB bus. When trace enable bit is set, CRC_CTRL2.CH1_MODE is automatically reset to 0 (data capture mode). To change from one mode to another mode in the middle of an on-going mode, perform the following steps:

1. Assert software reset for the respective channel.
2. Change from the current active mode to Data Capture mode (CRC_CTRL2.CH1_MODE = 0).
3. Change from Data Capture mode to the new mode.
4. Release software reset.

14.2.12 Power Down Mode

CRC module can be put into power down mode when the power down control bit PWDN is set. The module wakes up when the PWDN bit is cleared. When CRC controller is in power down mode, no data tracing alone will happen. However, if CRC registers are accessed then data trace happens from channel 1.

14.2.13 Emulation

A read access from a register in functional mode can sometimes trigger a certain internal event to follow. For example, reading an interrupt offset register triggers an event to clear the corresponding interrupt status flag. During emulation when SUSPEND signal is high, a read access from any register should only return the register contents to the bus and should not trigger or mask any event as it would have in functional mode. This is to prevent debugger from reading the interrupt offset register during refreshing screen and cause the corresponding interrupt status flag to get cleared. Timeout counters are stopped to generate timeout interrupts in emulation mode. No Peripheral Master bus error should be generated if reading from the unimplemented locations. When channel 1 is placed under data trace, the PSA Signature Register does not compress any data read on CPU data bus when suspend is active.

14.2.14 Peripheral Bus Interface

CRC is a Peripheral slave module. The register interface is similar to other peripheral modules. CRC supports following features:

- Different sizes of burst operation.
- Aligned and unaligned accesses.
- Abort is generated for any illegal address accesses.

14.3 Example

This section illustrates several of the ways in which the CRC Controller can be utilized to perform CRC.

14.3.1 Example: Auto Mode Using Time Based Event Triggering

A large memory area with 2Mbyte (256k doubleword) is to be checked in the background of CPU. CRC is to be performed every 1K byte (128 doubleword). Therefore there should be 2048 pre-recorded CRC values. For illustration purpose, we map channel 1 CRC Value Register to DMA channel 1 and channel 1 PSA Signature Register to DMA channel 2. Assume all DMA transfers are carried out in 64-bit transfer size.

14.3.1.1 DMA Setup

- Set up DMA channel 1 with the starting address from which the pre-determined CRC values are stored. Set up the destination address to the memory-mapped channel 1 CRC Value Register. Put the source address at post increment addressing mode and put the destination address at constant addressing mode. Use **hardware** DMA request for channel 1 to trigger a **frame** transfer.
- Set up DMA channel 2 with the source address from which the contents of memory to be verified. Set up the destination address to the memory-mapped channel 1 PSA Signature Register. Program the element transfer count to 128 and the frame transfer count to 2048. Put the source address at post increment addressing mode and put the destination address at constant address mode. Use **hardware** DMA request for channel 2 to trigger an entire **block** transfer.

14.3.1.2 Timer Setup

The timer can be any general-purpose timer that is capable of generating a time-based DMA request.

- Set up timer to generate DMA request associated with DMA channel 2. For example, an OS can set up the timer to generate a DMA request every 10ms.

14.3.1.3 CRC Setup

- Program the pattern count to 128.
- Program the sector count to 2048.
- For example, we want the entire 2Mbytes to be compressed within 5ms. We can program the block complete timeout pre-load (CRC_BCTOPLDx) value to 15625 ($5 \text{ ms} / (1 \text{ HCLK period} \times 64)$) if CRC is operating at 200 MHz.
- Enable AUTO mode and all interrupts.

After AUTO mode is selected, CRC Controller automatically generates a DMA request on channel 1. Around the same time the timer module also generates a DMA request on DMA channel 2. When the first incoming data pattern arrives at the PSA Signature Register, the CRC Controller will compress it. After some time, the DMA controller would update the CRC Value Register with a pre-determined value matching the calculated signature for the first sector of 128 64 bit data patterns. After one sector of data patterns are compressed, the CRC Controller generate a CRC fail interrupt if signature stored at the PSA Sector Signature Register does not match the CRC Value Register. CRC Controller generates a DMA request on DMA channel 1 when one sector of data patterns are compressed. This routine will continue until the entire 2Mbyte are consumed. If the timeout counter reached zero before the entire 2Mbytes are compressed a timeout interrupt is generated. After 2MBytes are transferred, the DMA can generate an interrupt to CPU. The entire operation will continue again when DMA responds to the DMA request from both the timer and CRC Controller. The CRC is performed totally without any CPU intervention.

14.3.2 Example: Auto Mode Without Using Time Based Triggering

A small but highly secured memory area with 1kbytes is to be checked in the background of CPU. CRC is to be performed every 1Kbytes. Therefore there is only one pre-recorded CRC value. For illustration purpose, we map channel 1 CRC Value Register to DMA channel 1 and channel 1 PSA Signature Register to DMA channel 2. Assume all transfers carried out by DMA are in 64 bit transfer size.

14.3.2.1 DMA Setup

- Set up DMA channel 1 with the source address from which the pre-determined CRC value is stored. Set up the destination address to the memory-mapped channel 1 CRC Value Register. Put the source address at constant addressing mode and put the destination address at constant addressing mode. Use **hardware** DMA request for channel 1.
- Set up DMA channel 2 with the source address from which the memory area to be verified. Set up the destination address to the memory-mapped channel 1 PSA Signature Register. Program the element transfer count to 128 and the frame transfer count to 1. Put the source address at post increment addressing mode and put the destination address at constant address mode. Generate a **software** DMA request on channel 2 after CRC has completed its setup. Enable autoinitiation for DMA channel 2.

14.3.2.2 CRC Setup

- Program the pattern count to 128.
- Program the sector count to 1.
- Leaving the timeout count register with the reset value of zero means no timeout interrupt is generated.
- Enable AUTO mode and all interrupts.

After AUTO mode is selected, the CRC Controller automatically generates a DMA request on channel 1. At the same time the CPU generates a **software** DMA request on DMA channel 2. When the first incoming data pattern arrives at the PSA Signature Register, the CRC Controller will compress it. After some time, the DMA controller would update the CRC Value Register with a pre-determined value matching the calculated signature for the first sector of 128 64 bit data patterns. After one sector of data patterns are compressed, the CRC Controller generates a CRC fail interrupt if signature stored at the PSA Sector Signature Register does not match the CRC Value Register. CRC Controller generates a DMA request on DMA channel 1 again after one sector is compressed. After 1kbytes are transferred, the DMA can generate an interrupt to CPU. Responding to the DMA interrupt CPU can restart the CRC routine by generating a software DMA request onto channel 2 again.

14.3.3 Example: Semi-CPU Mode

If DMA controller is available in a system, the CRC module can also operate in semi-CPU mode. This means that CPU can still make use of the DMA to perform data patterns transfer to CRC controller in the background. The difference between semi-CPU mode and AUTO mode is that CRC controller does not automatically perform the signature verification. CRC controllers generates a compression complete interrupt to CPU when the one sector of data patterns are compressed. CPU needs to perform the signature verification itself.

A memory area with 2Mbyte is to be verified with the help of the CPU. CRC operation is to be performed every 1K byte. Since there are 2Mbyte (256k doublewords) of memory to be check and we want to perform a CRC every 1Kbyte (128 doublewords) and therefore there should be 2048 pre-recorded CRC values. In Semi-CPU mode, the CRC Value Register is not updated and contains indeterminate data.

14.3.3.1 DMA Setup

Set up DMA channel 1 with the source address from which the memory area to be verified are mapped. Set up the destination address to the memory-mapped channel 1 PSA Signature Register. Put the starting address at post increment addressing mode and put the destination address at constant address mode. Use hardware DMA request to trigger an entire block transfer for channel 1. Disable autoinitiation for DMA channel 1.

14.3.3.2 Timer Setup

The timer can be any general-purpose timer that is capable of generating a time-based DMA request.

Set up timer to generate DMA request associated with DMA channel 1. For example, an OS can set up the timer to generate a DMA request every 10ms.

14.3.3.3 CRC Setup

- Program the pattern count to 128.
- Program the sector count to 2048.
- For example, we want the entire 2Mbytes to be compressed within 5ms. We can program the block complete timeout pre-load value to 15625 ($5 \text{ ms} / (1 \text{ HCLK period} \times 64)$) if CRC is operating at 200 MHz.
- Enable Semi-CPU mode and enable all interrupts.

The timer module first generates a DMA request on DMA channel 1 when it is enabled. When the first incoming data pattern arrives at the PSA Signature Register, the CRC controller will compress it. After one sector of data patterns are compressed, the CRC controller generate a compression complete interrupt. Upon responding to the interrupt the CPU would read from the PSA Sector Signature Register. It is up to the CPU on how to deal with the PSA value just read. It can compare it to a known signature value or it can write it to another memory location to build a signature file or even transfer the signature out of the device via SCI or SPI. This routine will continue until the entire 2Mbyte are consumed. The latency of the interrupt response from CPU can cause overrun condition. If CPU does not read from PSA Sector Signature Register before the PSA value is overridden with the signature of the next sector of memory, an overrun interrupt will be generated by CRC controller.

14.3.4 Example: Full-CPU Mode

In a system without the availability of DMA controller, the CRC routine can be operated by CPU provided the CPU has enough throughput. CPU needs to read from the memory area from which CRC is to be performed.

A memory area with 2Mbyte is to be checked with the help of the CPU. CRC verification is to be performed every 1K byte. In CPU mode, the CRC Value Register is not updated and contains indeterminate data.

14.3.4.1 CRC Setup

- All control registers can be left in their reset state. Only enable Full-CPU mode.

CPU itself reads from the memory and write the data to the PSA Signature Register inside CRC Controller. When the first incoming data pattern arrives at the PSA Signature Register, the CRC Controller will compress it. After **2MBytes** data patterns are compressed, CPU can read from the PSA Signature Register. It is up to the CPU on how to deal with the PSA signature value just read. It can compare it to a known signature value stored at another memory location.

14.4 CRC Control Registers

All registers are in word boundary. 64-, 32-, 16-, and 8-bit write accesses are supported to all registers. The base address for the control registers is FE00 0000h.

Table 14-4. CRC Control Registers

| Offset | Acronym | Register Description | Section |

| | | 1 | Compression Complete Interrupt is active |
| | | 0 | Privileged mode (write): Has no effect |
| | | 1 | Bit is cleared |

14.4.7 CRC Interrupt Offset (CRC_INT_OFFSET_REG)

Figure 14-15. CRC Interrupt Offset (CRC_INT_OFFSET_REG) [offset = 30h]

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 14-11. CRC Interrupt Offset (CRC_INT_OFFSET_REG) Field Descriptions

| Bit | Field | Value | Description |
|------|----------|---------|---|
| 31-8 | Reserved | 0 | Reads return 0. Writes have no effect. |
| 7-0 | OFSTREG | | CRC Interrupt Offset. This register indicates the highest priority pending interrupt vector address. Reading the offset register automatically clears the respective interrupt flag. |
| | | 0 | Phantom |
| | | 1h | Ch1 CRC Fail |
| | | 2h | Ch2 CRC Fail |
| | | 3h-8h | Reserved |
| | | 9h | Ch1 Compression Complete |
| | | Ah | Ch2 Compression Complete |
| | | Bh-10h | Reserved |
| | | 11h | Ch1 Overrun |
| | | 12h | Ch2 Overrun |
| | | 13h-18h | Reserved |
| | | 19h | Ch1 Underrun |
| | | 1Ah | Ch2 Underrun |
| | | 1Bh-20h | Reserved |
| | | 21h | Ch1 Timeout |
| | | 22h | Ch2 Timeout |
| | | 23h-FFh | Reserved |

14.4.8 CRC Busy Register (CRC_BUSY)

Figure 14-16. CRC Busy Register (CRC_BUSY) [offset = 38h]

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 14-12. CRC Busy Register (CRC_BUSY) Field Descriptions

| Bit | Field | Value | Description |
|------|----------|-------|---|
| 31-9 | Reserved | 0 | Reads return 0. Writes have no effect. |
| 8 | CH2_BUSY | | CH2_BUSY. During AUTO or Semi-CPU mode, the busy flag is set when the first data pattern of the block is compressed and remains set until the last data pattern of the block is compressed. The flag is cleared when the last data pattern of the block is compressed. |
| 7-1 | Reserved | 0 | Reads return 0. Writes have no effect. |
| 0 | CH1_BUSY | | CH1_BUSY. During AUTO or Semi-CPU mode, the busy flag is set when the first data pattern of the block is compressed and remains set until the last data pattern of the block is compressed. The flag is cleared when the last data pattern of the block is compressed. |

14.4.9 CRC Pattern Counter Preload Register 1 (CRC_PCOUNT_REG1)

Figure 14-17. CRC Pattern Counter Preload Register 1 (CRC_PCOUNT_REG1) [offset = 40h]

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 14-13. CRC Pattern Counter Preload Register 1 (CRC_PCOUNT_REG1) Field Descriptions

| Bit | Field | Value | Description |
|-------|----------------|-------|---|
| 31-20 | Reserved | 0 | Reads return 0. Writes have no effect. |
| 19-0 | CRC_PAT_COUNT1 | | Channel 1 Pattern Counter Preload Register. This register contains the number of data patterns in one sector to be compressed before a CRC is performed. |

14.4.10 CRC Sector Counter Preload Register 1 (CRC_SCOUNT_REG1)

Figure 14-18. CRC Sector Counter Preload Register 1 (CRC_SCOUNT_REG1) [offset = 44h]

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 14-14. CRC Sector Counter Preload Register 1 (CRC_SCOUNT_REG1) Field Descriptions

| Bit | Field | Value | Description |
|-------|----------------|-------|--|
| 31-16 | Reserved | 0 | Reads return 0. Writes have no effect. |
| 15-0 | CRC_SEC_COUNT1 | | Channel 1 Sector Counter Preload Register. This register contains the number of sectors in one block of memory. |

14.4.11 CRC Current Sector Register 1 (CRC_CURSEC_REG1)

Figure 14-19. CRC Current Sector Preload Register 1 (CRC_CURSEC_REG1) [offset = 48h]

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 14-15. CRC Current Sector Register 1 (CRC_CURSEC_REG1) Field Descriptions

| Bit | Field | Value | Description |
|-------|-------------|-------|--|
| 31-16 | Reserved | 0 | Reads return 0. Writes have no effect. |
| 15-0 | CRC_CURSEC1 | | Channel 1 Current Sector ID Register. In AUTO mode, this register contains the current sector number of which the signature verification fails. The sector counter is a free running up counter. When a sector fails, the erroneous sector number is logged into current sector ID register and the CRC fail interrupt is generated. The sector ID register is frozen until it is read and the CRC fail status bit is cleared by CPU. While it is frozen, it does not capture another erroneous sector number. When this condition happens, an overrun interrupt is generated instead. Once the register is read and the CRC fail interrupt flag is cleared it can capture new erroneous sector number. In Semi-CPU mode, this register is used to indicate the sector number for which the compression complete has last happened. |

14.4.12 CRC Channel 1 Watchdog Timeout Preload Register A (CRC_WDTPLD1)

Figure 14-20. CRC Channel 1 Watchdog Timeout Preload Register A (CRC_WDTPLD1)
[offset = 4Ch]

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 14-16. CRC Channel 1 Watchdog Timeout Preload Register A (CRC_WDTPLD1)
Field Descriptions

| Bit | Field | Value | Description |
|-------|-------------|-------|---|
| 31-24 | Reserved | 0 | Reads return 0. Writes have no effect. |
| 23-0 | CRC_WDTPLD1 | | Channel 1 Watchdog Timeout Counter Preload Register. This register contains the number of clock cycles within which the DMA must transfer the next block of data patterns. In Semi-CPU mode, this register is used to indicate the sector number for which the compression complete has last happened. |

14.4.13 CRC Channel 1 Block Complete Timeout Preload Register B (CRC_BCTOPLD1)

Figure 14-21. CRC Channel 1 Block Complete Timeout Preload Register B (CRC_BCTOPLD1)
[offset = 50h]

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 14-17. CRC Channel 1 Block Complete Timeout Preload Register B (CRC_BCTOPLD1)
Field Descriptions

| Bit | Field | Value | Description |
|-------|--------------|-------|---|
| 31-24 | Reserved | 0 | Reads return 0. Writes have no effect. |
| 23-0 | CRC_BCTOPLD1 | | Channel 1 Block Complete Timeout Counter Preload Register. This register contains the number of clock cycles within which the CRC for an entire block needs to complete before a timeout interrupt is generated. |

14.4.14 Channel 1 PSA Signature Low Register (PSA_SIGREGL1)

Figure 14-22. Channel 1 PSA Signature Low Register (PSA_SIGREGL1) [offset = 60h]

| 15.8 VIM Registers | 542 |

15.1 Overview

The vectored interrupt manager (VIM) provides hardware assistance for prioritizing and controlling the many interrupt sources present on a device. Interrupts are caused by events outside of the normal flow of program execution. Normally, these events require a timely response from the central processing unit (CPU); therefore, when an interrupt occurs, the CPU switches execution from the normal program flow to an interrupt service routine (ISR).

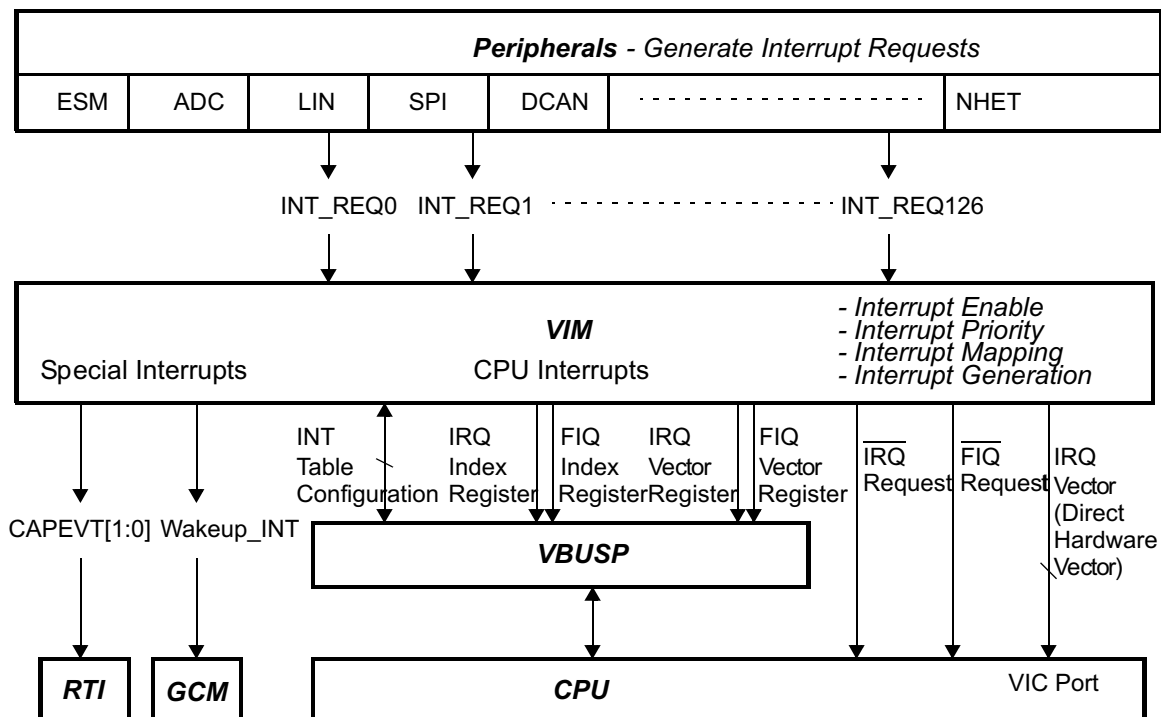

The VIM module has the following features:

- Supports 128 interrupt channels, in both register vectored interrupt and hardware vectored interrupt mode.
 - Provides IRQ vector directly to the CPU VIC port
 - Provides FIQ/IRQ vector through registers
 - Provides programmable priority and enable for interrupt request lines
- Provides a direct hardware dispatch mechanism for fastest IRQ dispatch.
- Provides two software dispatch mechanisms for backward compatibility with earlier generation of TI processors.
 - Index interrupt
 - Register vectored interrupt
- Parity protected vector interrupt table against soft errors.

15.2 Device Level Interrupt Management

A block diagram of device level interrupt handling is shown in [Figure 15-1](#). When an event occurs within a peripheral, the peripheral makes an interrupt request to the VIM. Then, VIM prioritizes the requests from peripherals and provides the address of the highest interrupt service routine (ISR) to the CPU. Finally, CPU starts executing the ISR instructions from that address in the ISR. [Section 15.2.1](#) through [Section 15.2.3](#) provide additional details about these three steps.

Figure 15-1. Device Level Interrupt Block Diagram

15.2.1 Interrupt Generation at the Peripheral

Interrupt generation begins when an event occurs within a peripheral module. Some examples of interrupt-capable events are expiration of a counter within a timer module, receipt of a character in a communications module, and completion of a conversion in an analog-to-digital converter (ADC) module. Some device peripherals are capable of requesting interrupts on more than one interrupt request line.

Interrupts are not always generated when an event occurs; the peripheral must make an interrupt request to the VIM based on the event occurrence. Typically, the peripheral contains:

- An interrupt flag bit for each event to signify the event occurrence.
- An interrupt enable bit to control whether the event occurrence causes an interrupt request to the VIM.

15.2.2 Interrupt Handling at the CPU

The ARM CPU provides two vectors for interrupt requests—fast interrupt requests (FIQs) and normal interrupt requests (IRQs). FIQs are higher priority than IRQs, and FIQ interrupts may interrupt IRQ interrupts.

NOTE: The FIQ implemented in Cortex-R4F is Non-Maskable Fast Interrupts (NMFI). Once FIQ is enabled (by clearing F bit in CPSR), it can NOT be disabled by setting F bit in CPSR. Only a reset or an FIQ will be able to set the F bit in CPSR. By hardware, Non Maskable FIQ are not reentrant.

After reset (power reset or warm reset), both FIQ and IRQ are disabled. The CPU may enable these interrupt request channels individually within the CPSR (Current Program Status Register); CPSR bits 6 and 7 must be cleared to enable the FIQ (bit 6) and IRQ (bit 7) interrupt requests at the CPU. CPSR is writable in privilege mode only. [Example 15-2](#) shows how to enable the IRQ and FIQ through CPSR.

When the CPU receives an interrupt request, the CPSR mode field changes to either FIQ or IRQ mode. When an IRQ interrupt is received, the CPU disables other IRQ interrupts by setting CPSR bit 7. When an FIQ interrupt is received, the CPU disables both IRQ and FIQ interrupts by setting CPSR bits 6 and 7.

A write of 1 to CPSR bit 7 disables the IRQ from CPU. However, a write of 1 to CPSR bit 6 leaves it unchanged. [Example 15-2](#) also shows how to disable the IRQ through CPSR.

15.2.3 Software Interrupt Handling Options

The device supports three different possibilities for software to handle interrupts

1. Index interrupts mode (compatible with TMS470R1x legacy code)

After the interrupt is received by the CPU, the CPU branches to 0x18 (IRQ) or 0x1C (FIQ) to execute the main ISR. The main ISR routine reads the offset register (IRQINDEX, FIQINDEX) to determine the source of the interrupt.

This mode is compatible with the TMS470R1x (CIM) module and provides the same interrupt registers.

This mode could be used if legacy code needs to be reused, porting it from the TMS470R1x family. However, imported software will not benefit from the VIM improvements.

To port legacy software, the interrupt vector at 0x18 (IRQ) or 0x1C (FIQ) only needs to be a branch statement to a software interrupt table. The software interrupt table reads the pending interrupt from a vector offset register (FIQINDEX[7:0] for FIQ interrupts and IRQINDEX[7:0] for IRQ interrupts). All pending interrupts can be viewed in the INTREQ register. [Example 15-4](#) shows how to respond to FIQ with short latency in this mode.

2. Register vectored interrupts (automatically provide vector address to application)

Before enabling interrupts, the application software also has to initiate the interrupt vector table (VIM RAM).

Once the VIM receives an interrupt, it loads the address of ISR from interrupt vector table, and store it into the interrupt vector register (IRQVECREG for IRQ interrupt, FIQVECREG for FIQ interrupt).

After the interrupt is received by the CPU, the CPU executes the instruction placed at 0x18 or 0x1C (IRQ or FIQ vector) to load the address of ISR (interrupt vector) from the interrupt vector register.

[Example 15-3](#) illustrates the configuration for the exception vectors using this mode.

3. Hardware vectored interrupts (automatically dispatch to ISR, IRQ only)

Before enabling interrupts, the application software must initiate the interrupt vector table (VIM RAM) pointing to the ISR for each interrupt channel.

After the interrupt (IRQ) is received by the CPU, CPU reads the address of ISR directly from the interface with VIM (VIC port) instead of branching to 0x18. The CPU will branch directly to the ISR.

The hardware vectored interrupt behavior must be explicitly enabled by setting the vector enable (VE) bit in the CP15 R1 register. This bit resets to 0, so that the default state after reset is backward compatible to earlier ARM CPU. [Example 15-1](#) shows how to enable the hardware vectored interrupt.

NOTE: This mode is NOT available for FIQ.

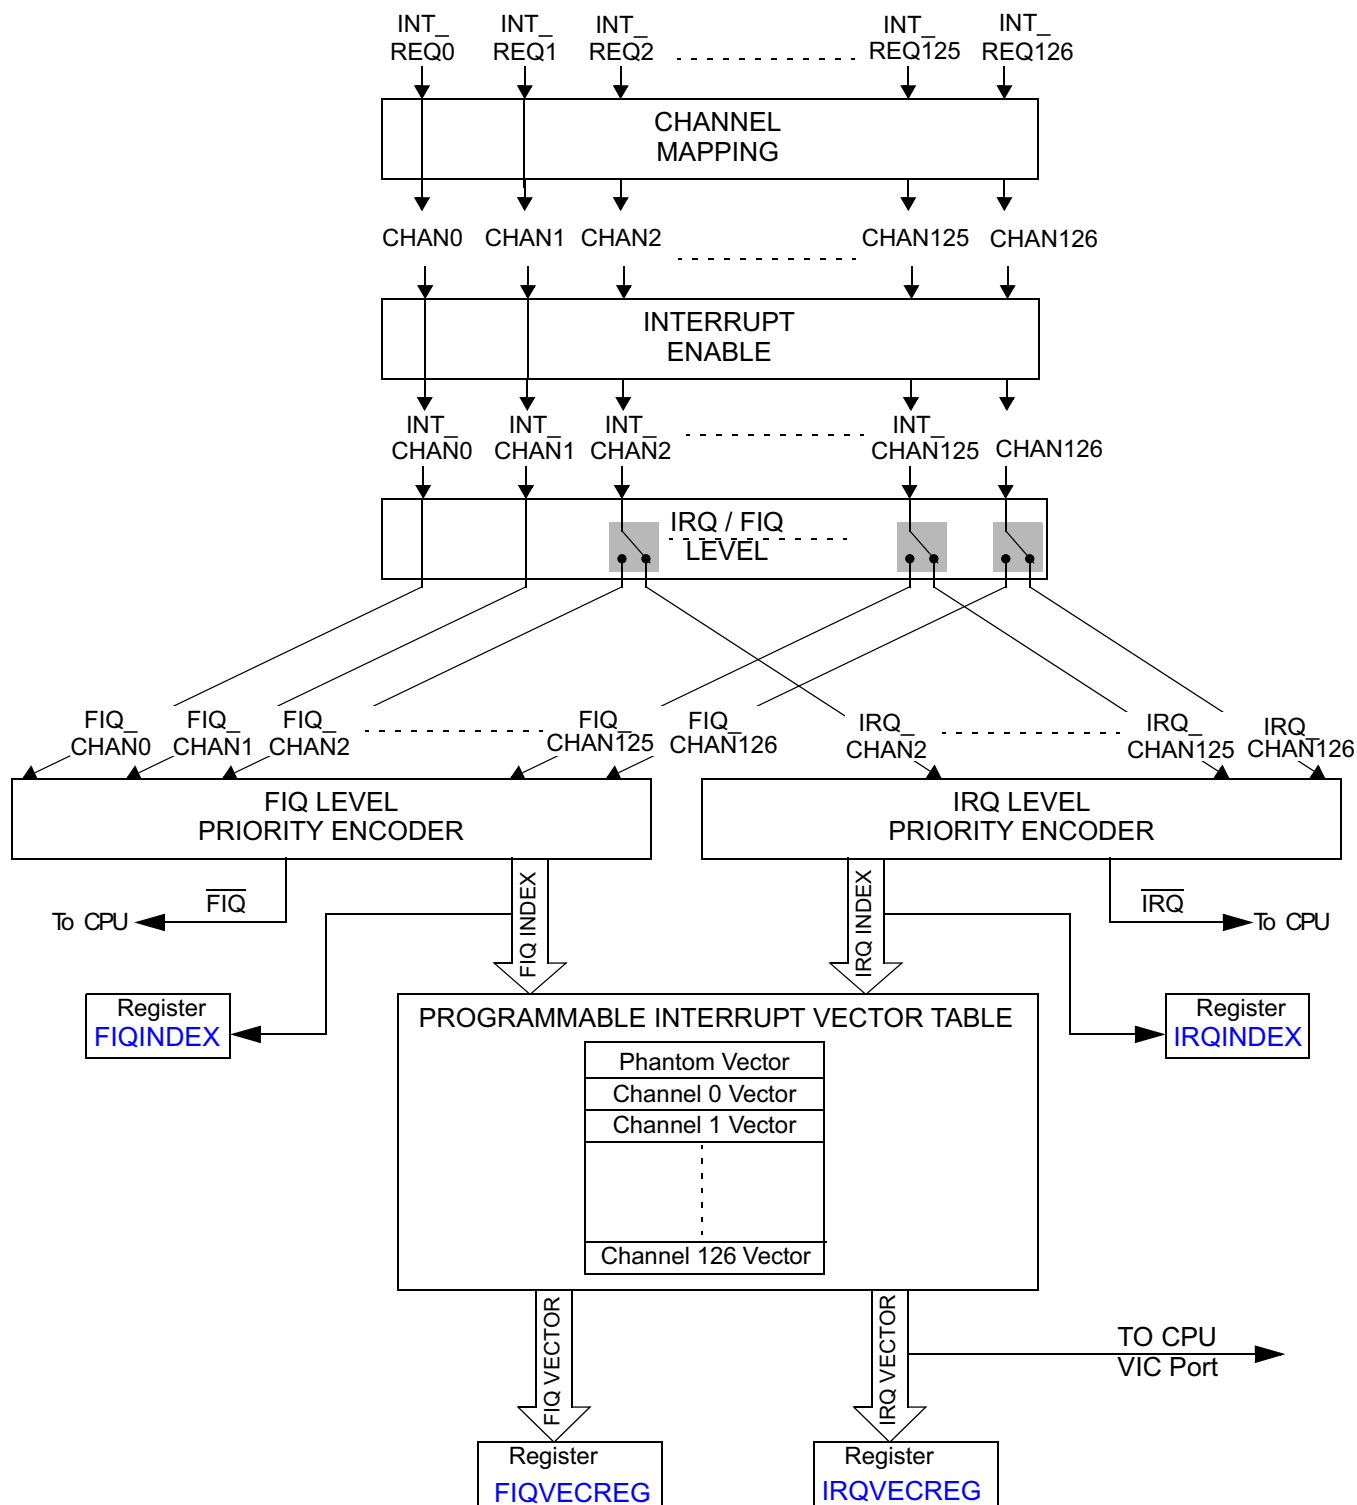

4. Software-Based Priority Decoding Scheme

If the application uses a software-based interrupt priority decoding scheme instead of the hardware vector capabilities, then there is an additional step which was not required on earlier devices. This version of the VIM will hold an interrupt request generated by a peripheral. When the software clears the interrupt condition in the source module (for example, RTI, GIO, and so on), then it must also perform an additional clear of the interrupt request in the VIM. This can be done by reading the IRQVECREG register ([Section 15.8.12](#)) or FIQVECREG register ([Section 15.8.13](#)), or by writing a 1 to the INTREQ(i) bit ([Section 15.8.7](#)) in the VIM. This is not necessary if any of the three previous methods are used as the interrupt request bit in the VIM will be automatically cleared when the vector is read.

15.3 Interrupt Handling Inside VIM

A block diagram of the interrupt handling inside VIM is shown in [Figure 15-2](#)

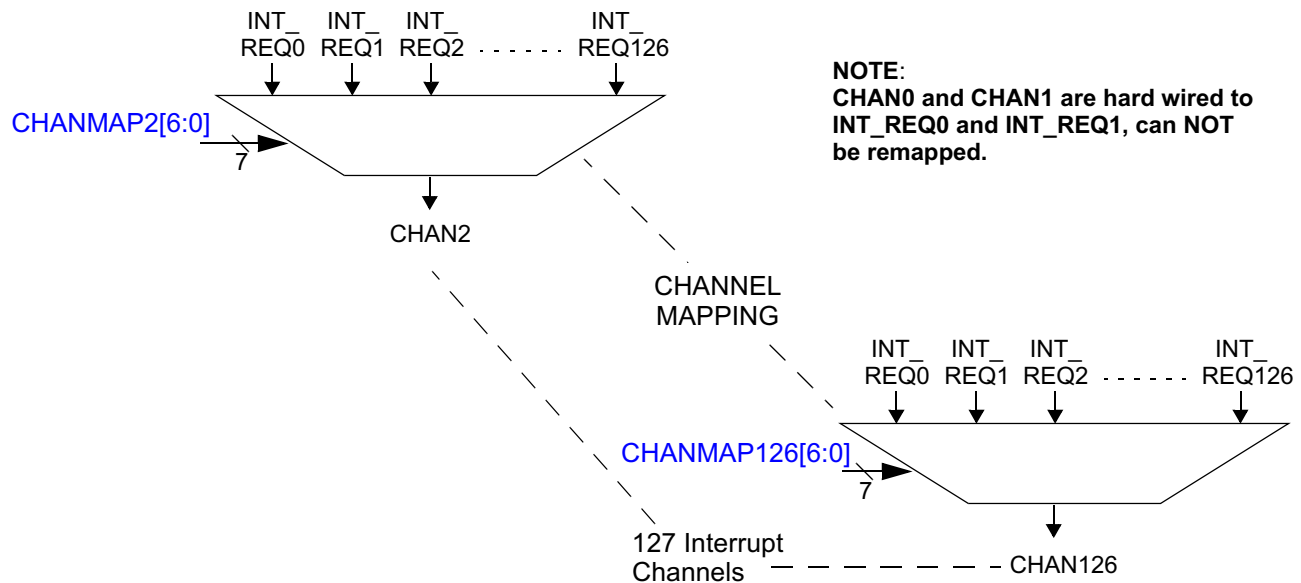

Figure 15-2. VIM Interrupt Handling Block Diagram

15.3.1 VIM Interrupt Channel Mapping

The VIM supports 128 interrupt channels (including phantom interrupt). A block diagram of the VIM interrupt requests arrangement from peripheral modules to the interrupt channels is provided in [Figure 15-3](#). Each interrupt channel (CHANx) has a corresponding mapping register bit field (CHANMAPx[6:0]). This mapping register determines which interrupt channel it maps each VIM interrupt request. With this scheme, the same request can be mapped to multiple channels. A lower numbered channel in each FIQ and IRQ has higher priority. The programmability of the VIM allows software to control the interrupt priority.

Figure 15-3. VIM Channel Mapping

NOTE: CHAN127

CHAN127 has no dedicated interrupt vector table entry. Therefore, CHAN127 shall NOT be remapped to other INT_REQ (INT_REQ127 is reserved at device level).

In the reset state, the VIM maps all of the interrupt requests in the system to their respective interrupt channels. [Figure 15-4](#) shows the default state following the reset.

[Figure 15-5](#) shows the VIM INT2 is remapped to both Channel 2 and 4, and INT3 is mapped to channel 3.

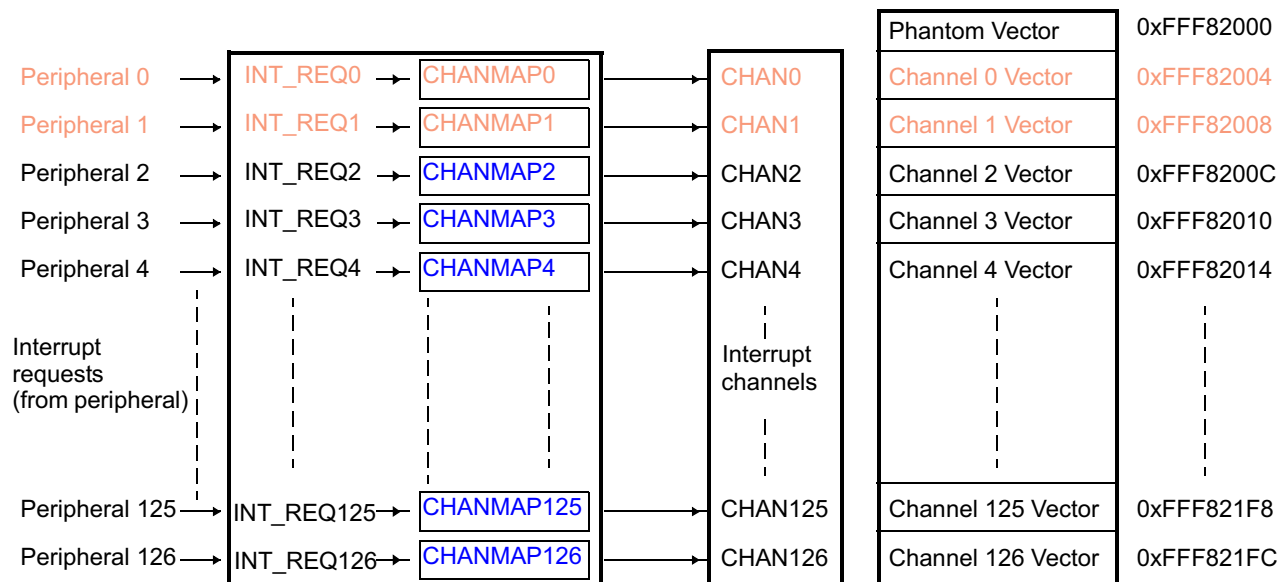

NOTE: By mapping INT2 to channel 2 and channel 4, and mapping INT3 to channel 3, it is possible for the software to change the priority dynamically by changing the ENABLE register (REQENASET and REQENACLR). When channel 2 is enabled, the priority is:

1. INT0
2. INT1
3. INT2
4. INT3

Disabling channel 2, the priority becomes:

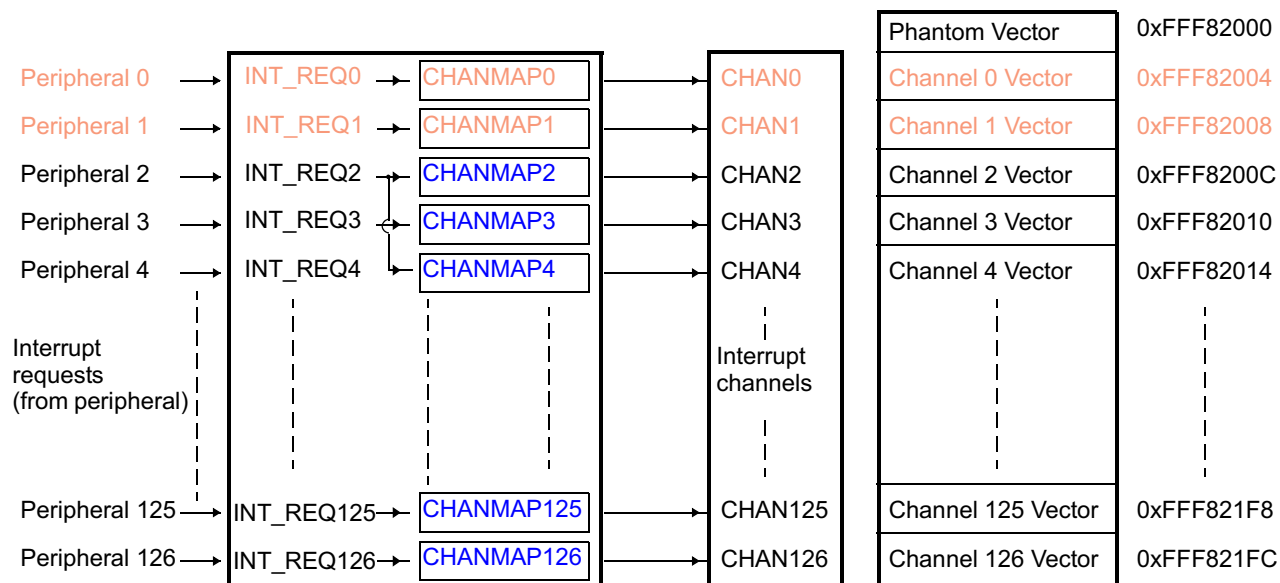

1. INT0
2. INT1
3. INT3
4. INT2

Figure 15-4. VIM in Default State

NOTE: CHAN0 and CHAN1 are hardwired to INT_REQ0 and INT_REQ1, so they cannot be remapped.

Figure 15-5. VIM in a Programmed State

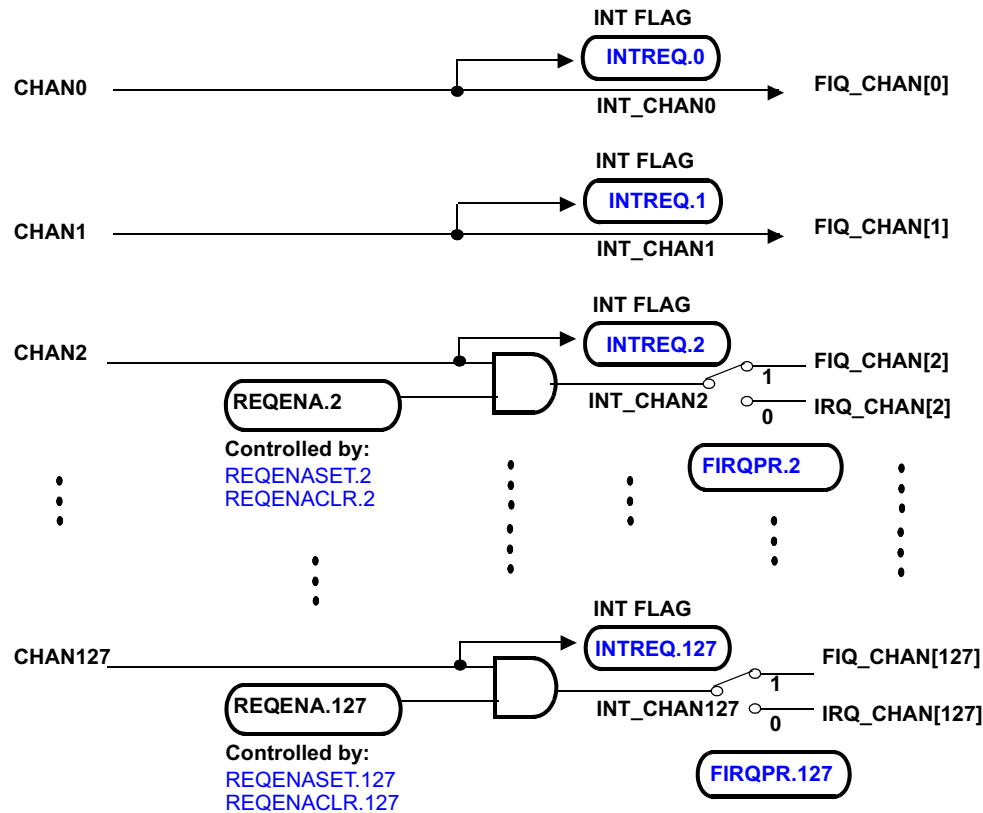

NOTE: CHAN0 and CHAN1 are hard wired to INT_REQ0 and INT_REQ1, so they cannot be remapped.

15.3.2 VIM Input Channel Management

As shown in Figure 15-6, the VIM enables channels on a channel-by-channel basis (in the REQENASET and REQENACLR registers); unused channels may be masked to prevent spurious interrupts.

NOTE: The interrupt ENABLE register does not affect the value of INTREQ.

Figure 15-6. Interrupt Channel Management

By default, interrupt CHAN0 is mapped to ESM (Error Signal Module) high level interrupt and CHAN1 is reserved for other NMI. For safety reasons, these two channels are mapped to FIQ only and can **NOT** be disabled through ENABLE registers.

NOTE: NMI Channel

Channel 0 and channel 1 are not maskable by the REQENASET and REQENACLR bit and both channel are routed exclusively to FIQ/NMI request line (FIRQPR0 and FIRQPR1 have no effect).

The VIM prioritizes the received interrupts based upon a programmed prioritization scheme. The VIM can send two interrupt requests to the CPU simultaneously—one IRQ and one FIQ. If both interrupt types are enabled at the CPU level, then the FIQ has greater priority and is handled first. Each interrupt channel, except channel 0 and 1, can be assigned to send either an FIQ or IRQ request to the CPU (in the FIRQPR register).

The VIM provides a default prioritization scheme, which sends the lowest numbered active channel (in each FIQ and IRQ classes) to the CPU. Within the FIQ and IRQ classes of interrupts, the lowest channel has the highest priority interrupt. The channel number is programmable through register CHANMAPx.

After the VIM has generated the vector corresponding to the highest active IRQ, it updates the FIQINDEX or the IRQINDEX register, depending on the class of interrupt. Then, it accesses the interrupt vector table using the vector value to fetch the address of the corresponding ISR. If the request is an FIQ class interrupt, the address read from the interrupt vector table, is written to the FIQVECREG register. If the request is an IRQ class interrupt, the address is written to the IRQVECREG register and put on the VIC port of the CPU (in case of hardware vectored interrupt is enabled).

All of the interrupt registers are updated when a new high priority interrupt line becomes active.

15.4 Interrupt Vector Table (VIM RAM)

Interrupt vector table stores the address of ISRs. During register vectored interrupt and hardware vectored interrupt, VIM accesses the interrupt vector table using the vector value to fetch the address of the corresponding ISR.

For safety reasons, the interrupt vector table has protection by parity to indicate corruption due to soft errors. The parity scheme is implemented as a continuous background check based on memory access. [Section 15.4.1](#) through [Section 15.4.4](#) describe how parity works in the interrupt vector table.

15.4.1 Interrupt Vector Table Operation

The interrupt vector table is organized in 128 words of 32 bits. 32-bit, 16-bit, and 8-bit accesses are supported (when parity is disabled). [Figure 15-7](#) shows the interrupt memory mapping. The table base address is FFF8 2000h.

Figure 15-7. VIM Interrupt Address Memory Map

Interrupt vector table address space

| | |
|-------------|--------------------|
| 0xFFFF82000 | Phantom Vector |
| 0xFFFF82004 | Channel 0 Vector |
| 0xFFFF82008 | Channel 1 Vector |
| | |
| | |
| | |
| | |
| | |
| | |
| | |
| | |
| | |
| 0xFFFF821F8 | Channel 125 Vector |
| 0xFFFF821FC | Channel 126 Vector |

NOTE: The interrupt vector table only has 128 entries, one phantom vector and 127 interrupt channels. Channel 127 does not have a dedicated vector and shall not be used.

There is one bit of parity per 32-bit ISR address. When a write is performed into the interrupt vector table, the parity is calculated for the 32-bit word and a parity bit is written into the corresponding parity region of interrupt vector table.

NOTE: Only 32-bit write/read access are allowed on interrupt vector table if parity is required. Non 32-bit access might result in parity errors.

When a read occurs from the CPU or VIM, the VIM calculates the parity from the data coming from the interrupt vector table and compares it to the parity stored in the table. The access of the data and the parity is performed in the same clock cycle.

If the parity bit does not match the calculated parity, a parity error is generated and the VIM stores the address of the error in the ADDERR register. The parity flag error (PARFLG) is set.

NOTE: The PARFLG register is only for bypassing the interrupt vector table in case of a parity fault. It should be used only to maintain the interrupt vector table bypassed. The checking of the parity fault should be done in the error signaling module (ESM) module where all parity errors are flagged.

Since the interrupt vector table may have an error, the FBPARERR register will provide to the VIC port, IRQVECREG and FIQVECREG, a fall-back address to an ISR that can restore the interrupt vector table content. The FBPARERR register should be set before initializing the interrupt in the interrupt vector table, to avoid branching to an unpredictable location.

The normal operation is restored when the PARFLG is cleared by the CPU. It is recommended to restore the content of the VIM before clearing the PARFLG.

The parity error signal is forwarded to the ESM.

15.4.2 Enabling and Controlling the VIM Parity

The polarity of VIM parity is controlled by the DEVCR1 register in the system module (address FFFF FFDCh). The parity enable is controlled by the PARCTL register. After reset, the parity is disabled.

Parity checking can be enabled by writing 0xA (1010b) in the PARENA[3:0] bit field of the PARCTL register. The default polarity is odd. The polarity can be changed to even by writing 5 (0101b) in the DEVPARSEL[3:0] bit field of the DEVCR1 register.

15.4.3 Interrupt Vector Table Initialization

After reset, the interrupt vector table content, including the parity bits is not initialized. Therefore, the CPU need to initialize all of the interrupt addresses into the table, before enabling the corresponding interrupt channel. If parity is required, this initialization should be done after the parity functionality is enabled. In this way, the corresponding parity bit will be automatically updated. This initialization is only required when vectored interrupts are used, index interrupt management does not need the table to be initialized.

15.4.4 Interrupt Vector Table Parity Testing

To test the parity checking mechanism, the parity RAM allows manual insertion of faults. This option is implemented by the test bit in the PARCTL register. Once the bit is set, the parity bits are mapped to 0xFFFF82400. After that, user can force faults into the parity bits. Finally, the parity error can be triggered by reading interrupt vector table (not parity bit) from VIM or CPU.

The interrupt vector table parity can also be verified by inserting faults into interrupt vector table. Once the VIM parity is disabled in system module, user can modify interrupt vector table without impacting the parity bit. After user re-enable interrupt vector table parity, the parity error can be triggered by reading interrupt vector table from VIM or CPU.

Figure 15-8. Parity Bit Mapping

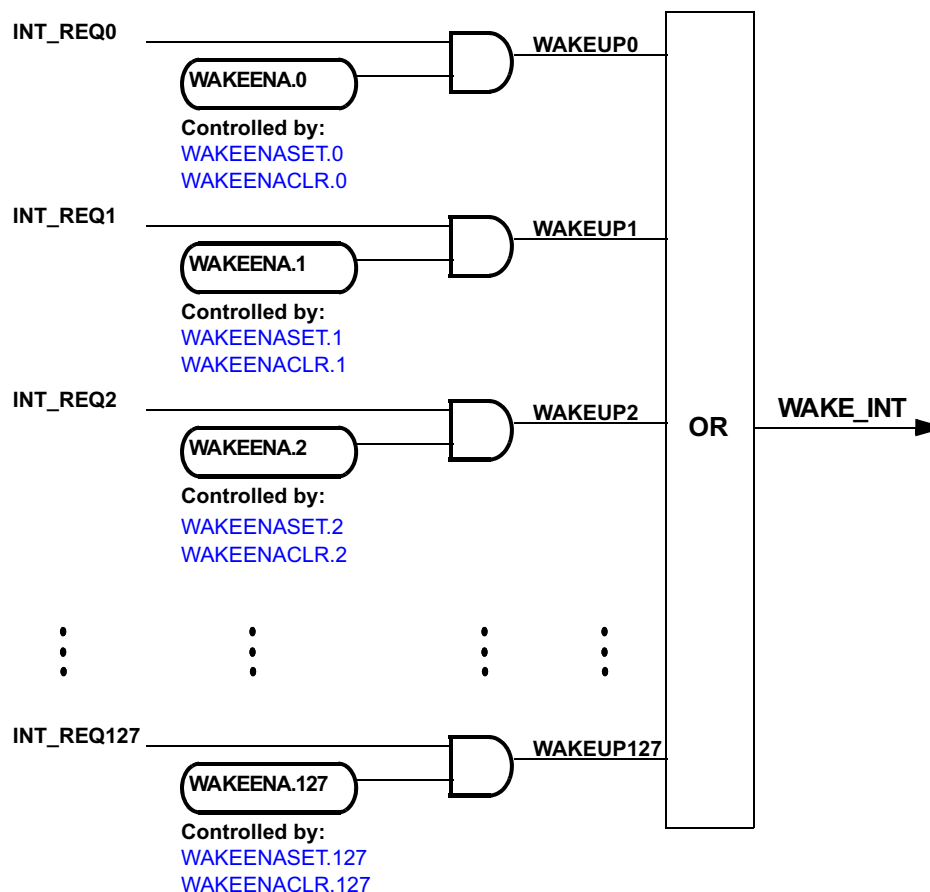

15.5 VIM Wakeup Interrupt

The wakeup interrupts are used to come out of low power mode (LPM). Any interrupt requests can be used to wake up the device. After reset, all interrupt requests are set to wake up from LPM. However, the VIM can mask unwanted interrupt lines for wake-up by using the WAKEENASET and WAKEENACLR register. The value in REQENASET / REQENACLR does NOT impact the wakeup interrupt.

As shown in [Figure 15-9](#), the WAKEENASET and WAKEENACLR registers will enable/disable an interrupt for wake-up from low-power mode. All wake-up interrupts are “ORed” into a single signal WAKE_INT connected to the Global Clock Module.

Figure 15-9. Detail of the IRQ Input

15.6 Capture Event Sources

The VIM can select any of the 128 interrupt requests to generate up to two capture events for the real-time interrupt (RTI) module (see [Figure 15-10](#)). The value in REQENASET / REQENACLR does NOT impact the capture event. Two registers ([Section 15.8.14](#)) are available, one for each capture event source.

Figure 15-10. Capture Event Sources

15.7 Examples

The following sections provide examples about the operation of the VIM.

15.7.1 Examples - Configure CPU to Receive Interrupts

[Example 15-1](#) shows how to set the vector enable (VE) bit in the CP15 R1 register to enable the hardware vector interrupt. [Example 15-2](#) shows how to enable/disable the IRQ and FIQ through CPSR. As a convention, the program who calls these subroutines shall preserve register R1 if needed. [Example 15-2](#) can ONLY run in privileged mode. However, in USER mode, the application software can force the program into software interrupt by instruction 'SWI'. Then, in the software interrupt service routine, user can write register SPSR, which is the copy of CPSR in this exception mode.

Example 15-1. Enable Hardware Vector Interrupt (IRQ Only)

```
_HW_Vec_Init
    MRC p15 ,#0 ,R1 ,c1 ,c0 ,#0
    ORR R1 ,R1 ,#0x01000000      ; Mask 0-31 bits except bit 24 in Sys
                                ; Ctrl Reg of CORTEX-R4
    MCR p15 ,#0 ,R1 ,c1 ,c0 ,#0 ; Enable bit 24
    MOV PC, LR
```

Example 15-2. Enable/Disable IRQ/FIQ through CPSR

```

FIQENABLE .equ 0x40
IRQENABLE .equ 0x80
.....
_Enable_Fiq
    MRS R1, CPSR
    BIC R1, R1, #FIQENABLE
    MSR CPSR, R1
    MOV PC, LR
.....
_Disable_Irq
    MRS R1, CPSR
    ORR R1, R1, #IRQENABLE
    MSR CPSR, R1
    MOV PC, LR
.....
_Enable_Irq
    MRS R1, CPSR
    BIC R1, R1, #IRQENABLE
    MSR CPSR, R1
    MOV PC, LR

```

15.7.2 Examples - Register Vector Interrupt and Index Interrupt Handling

Example 15-3 illustrates the configuration for the exception vectors in Register Vector Interrupt handling. After the interrupt is received by the CPU, the CPU branches to 0x18 (IRQ) or 0x1C (FIQ). The instruction placed here should be *LDR PC, [PC, #-0x1B0]*. The pending ISR address is written into the corresponding vector register (IRQVECREG for IRQ, FIQVECREG for FIQ). The CPU reads the content of the register and branches to the ISR.

Example 15-3. Exception Vector Configuration for VIM Vector

```

        .sect ".intvecs"
00000000h b _RESET           ; RESET interrupt
00000004h b _UNDEF_INST_INT  ; UNDEFINED INSTRUCTION interrupt
00000008h b _SW_INT         ; SOFTWARE interrupt
0000000Ch b _ABORT_PREF_INT ; ABORT (PREFETCH) interrupt
00000010h b _ABORT_DATA_INT ; ABORT (DATA) interrupt
00000014h b #-8             ; Reserved
00000018h ldr pc,[pc, #-0x1B0] ; IRQ interrupt
0000001Ch ldr pc,[pc, #-0x1B0] ; FIQ interrupt

```

NOTE: Program Counter (PC) always pointers two instructions beyond the current executed instruction. In this case, PC equals to '0x18 or 0x1C + 0x08'. The *LDR* instruction load the memory at 'PC - 0x1B0', which is '0x18 or 0x1C + 0x08 - 0x1B0 = 0xFFFFFE70 or 0xFFFFFE74'. These are the address of IRQVECREG and FIQVECREG, which store the pending ISR address.

[Example 15-4](#) shows a fast response to the FIQ interrupt in Index Interrupt and can be applied to a system that has more than one channel assigned as a FIQ. It is built in Index Interrupt compatible with TMS470R1x legacy code.

Example 15-4. How to Respond to FIQ With Short Latency

```

        .sect ".intvecs"                ; Interrupt and exception vector sector
00000000h b _RESET                      ; RESET interrupt
00000004h b _UNDEF_INST_INT             ; UNDEFINED INSTRUCTION interrupt
00000008h b _SW_INT                     ; SOFTWARE interrupt
0000000Ch b _ABORT_PREF_INT             ; ABORT (PREFETCH) interrupt
00000010h b _ABORT_DATA_INT             ; ABORT (DATA) interrupt
00000014h b #-8                         ; Reserved
00000018h b _IRQ_ENTRY_0                ; IRQ interrupt
                                           ; *****
                                           ; INTERRUPT PROCESSING AREA
                                           ; *****
0000001Ch ldrb R8, [PC, #-0x21d]          ; FIQ INTERRUPT ENTRY
                                           ; R8 used to get the FIQ index
                                           ; with address pointer to the
                                           ; first FIQ banked register
00000020h ldr PC, [PC, R8, LSL#2]        ; Branch to the indexed interrupt
                                           ; routine. The prefetch
                                           ; operation causes the PC to be 2
                                           ; words (8 bytes) ahead of the
                                           ; current instruction, so
                                           ; pointing to _INT_TABLE.
00000024h nop                           ; Required due to pipeline.
                                           ; =====
00000028h _INT_TABLE                    ; FIQ INTERRUPT DISPATCH
                                           ; =====
0000002Ch .word _FIQ_TABLE               ; beginning of FIQ Dispatch
00000030h .word _ISR1                   ; dispatch to interrupt routine 1
00000034h .word _ISR2                   ; dispatch to interrupt routine 2
        .
        .

```

Another way to improve the FIQ latency is to assign only one channel to the FIQ interrupt and to map the ISR code corresponding to this channel directly starting at 0x1C.

NOTE: When the CPU is in vector-enabled mode, [Example 15-3](#) and [Example 15-4](#) are still valid. The difference is that the CPU will not read from the 0x18 location during IRQ interrupt, but will jump directly to the corresponding ISR routine.

15.8 VIM Registers

Table 15-1 lists the VIM module registers. Each register begins on a word boundary. All registers are 32-bit, 16-bit, and 8-bit accessible for read and write. Write is only possible in privilege mode. The base address of the VIM module is FFFF FE00h. The base address of the parity-related VIM registers is FFFF FD00h. The address locations not listed are reserved.

Table 15-1. VIM Control Registers

| Offset | Acronym | Register Description | Section |
|---------------------------------|-------------------------|--|----------------------------------|
| Parity-related Registers | | | |
| ECh | PARFLG | Interrupt Vector Table Parity Flag Register | Section 15.8.1 |

15.8.1 Interrupt Vector Table Parity Flag Register (PARFLG)

Figure 15-11 and Table 15-2 describe this register.

Figure 15-11. Interrupt Vector Table Parity Flag Register (PARFLG) [Address = FFFF FDECh]

| | | | | | | | | | | | | | | | | |
|-----|----------|--|--|--|--|--|--|--|--|--|--|--|--|--------|---|----|
| 31 | Reserved | | | | | | | | | | | | | | | 16 |
| R-0 | | | | | | | | | | | | | | | | |
| 15 | Reserved | | | | | | | | | | | | | | 1 | 0 |
| R-0 | | | | | | | | | | | | | | PARFLG | | |
| R-0 | | | | | | | | | | | | | | R/WP-0 | | |

LEGEND: R/W = Read/Write; R = Read only; WP = Write in privilege mode only; -n = value after reset

Table 15-2. Interrupt Vector Table Parity Flag Register (PARFLG) Field Descriptions

| Bit | Field | Value | Description |
|------|----------|-------|--|
| 31-1 | Reserved | 0 | Read returns 0. Writes have no effect. |
| 0 | PARFLG | 0 | The PARFLG indicates that a parity error has been found and that the Interrupt Vector Table is bypassed. The resulting vector of any IRQ/FRQ interrupt is then the value contained in the FBPARERR register until this bit has been cleared. Read: No parity error has occurred. Write: A write to this bit has no effect. |
| | | 1 | Read: A parity error has occurred and the Interrupt Vector Table is bypassed. Write: The PARFLG is cleared and the interrupt vector can be read from the Interrupt Vector Table. |

15.8.2 Interrupt Vector Table Parity Control Register (PARCTL)

Figure 15-12. Interrupt Vector Table Parity Control Register (PARCTL) [Address = FFFF FDF0h]

| | | | | | | | | | | | | | | | | |
|----------|--|--|--|--|--|--|--|--------|---|----------|-----|--|--|---------|--------|----|

LEGEND: R/W = Read/Write; R = Read only; WP = Write in privilege mode only; -n = value after reset

Table 15-3. Interrupt Vector Table Parity Control Register (PARCTL) Field Descriptions

| Bit | Field | Value | Description |
|------|----------|------------------|---|
| 31-9 | Reserved | 0 | Read returns 0. Writes have no effect. |
| 8 | TEST | 0 | This bit maps the parity bits into the Interrupt Vector Table frame to make them accessible by the CPU. Parity bits are not memory mapped. |
| | | 1 | Parity bits are memory mapped. |
| 7-4 | Reserved | 0 | Read returns 0. Writes have no effect. |
| 3-0 | PARENA | 5h | VIM parity enable. The VIM parity is disabled. |
| | | All other values | The VIM parity is enabled. Note: To avoid soft error to disable VIM parity checking, it is recommended to write Ah to enable parity checking. |

15.8.3 Address Parity Error Register (ADDERR)

The address parity error register gives the address of the first parity error location.

NOTE: No computation is needed when reading the complete register to retrieve the address in the Interrupt Vector Table.

This register will never be reset by a power-on reset nor any other reset source.

Figure 15-13. Address Parity Error Register (ADDERR) [Address = FFFF FDF4h]

| | | | | | | | | | | | | | | | | |
|-------------------------------|--|--|--|--|--|--|--|--------|---|--|--|--|---|-------------|---|----|
| 31 | | | | | | | | | | | | | | | | 16 |
| Interrupt Vector Table offset | | | | | | | | | | | | | | | | |

| R-20h | | | | | | | | R-x | | | | | | R-0 | | |

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 15-4. Address Parity Error Register (PARERR) Field Descriptions

| Bit | Field | Description |
|------|-------------------------------|---|
| 31-9 | Interrupt Vector Table offset | Interrupt Vector Table offset. Reads are always FF F820h; writes have no effect |
| 8-2 | ADDERR | Address parity error register. This register gives the address of the first encountered parity error since the flag has been clear. Subsequent parity errors will not update this register until the PARFLG register has been cleared. Note: This register is valid only when PARFLG is set (see Section 15.8.1). |
| 1-0 | Word offset | Word offset. Reads are always 0; writes have no effect. |

15.8.4 Fall-Back Address Parity Error Register (FBPARERR)

This register provides a fall-back address to the VIM if a parity error has occurred in the Interrupt Vector Table. Figure 15-14 and Table 15-5 describe this register.

NOTE: This register will never be reset by a power-on reset nor any other reset source.

Figure 15-14. Fall-Back Address Parity Error Register (FBPARERR) [Address = FFFF FDF8h]

| | | | | | | | | | | | | | | | | |
|----------|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|----|
| 31 | | | | | | | | | | | | | | | | 16 |

| R/WP-x | | | | | | | | | | | | | | | | |
| 15 | | | | | | | | | | | | | | | | 0 |
| FBPARERR | | | | | | | | | | | | | | | | |
| R/WP-x | | | | | | | | | | | | | | | | |

LEGEND: R/W = Read/Write; R = Read only; WP = Write in privilege mode only; -n = value after reset; x = Indeterminate

Table 15-5. Fall Back Address Parity Error Register (FBPARERR) Field Descriptions

| Bit | Field | Value | Description |
|------|----------|--------------|---|
| 31-0 | FBPARERR | 0-FFFF FFFFh | Fall back address parity error. This register is used by the VIM if the Interrupt Vector Table has been corrupted. The contents of the IRQVECREG and FIQVECREG registers will reflect the value programmed in FBPARERR. The value provided to the VIC port will also reflect FBPARERR until the PARFLG register has been cleared. This register provides the address of the ISR that will restore the integrity of the Interrupt Vector Table. |

15.8.5 VIM Offset Vector Registers

The VIM offset register provides the user with the numerical index value that represents the pending interrupt with the highest precedence. The register IRQINDEX holds the index to the highest priority IRQ interrupt; the register FIQINDEX holds the index to the highest priority FIQ interrupt. The index can be used to locate the interrupt routine in a dispatch table, as shown in [Table 15-6](#).

Table 15-6. Interrupt Dispatch

| IRQINDEX / FIQINDEX Register Bit Field | Highest Priority Pending Interrupt Enabled |
|--|--|
| 0x00 | No interrupt |
| 0x01 | Channel 0 |
| : | : |
| 0x7F | Channel 126 |
| 0x80 | Channel 127 |

NOTE: Channel 127 has no dedicated interrupt vector table entry. Therefore, Channel 127 shall NOT be used in application.

The VIM offset registers are read only. They are updated continuously by the VIM. When an interrupt is serviced, the offset vectors show the index for the next highest pending interrupt or 0x0 if no interrupt is pending.

15.8.5.1 IRQ Index Offset Vector Register (IRQINDEX)

The IRQ offset register provides the user with the numerical index value that represents the pending IRQ interrupt with the highest priority. [Figure 15-15](#) and [Table 15-7](#) describe this register.

Figure 15-15. IRQ Index Offset Vector Register (IRQINDEX) [Address = FFFF FE00h]

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 15-7. IRQ Index Offset Vector Register (IRQINDEX) Field Descriptions

| Bit | Field | Value | Description |
|------|----------|-------|--|
| 31-8 | Reserved | 0 | Read returns 0. Writes have no effect. |
| 7-0 | IRQINDEX | 0-FFh | IRQ index vector. The least-significant bits represent the index of the IRQ pending interrupt with the highest precedence, as shown in Table 15-6 . When no interrupts are pending, the least significant byte of IRQINDEX is 0. Note: A read of register IRQINDEX or IRQVECREG will cause IRQINDEX / IRQVECREG to reflect the index/ISR address for the next highest-priority pending IRQ interrupt. In case there is no other interrupt pending, the IRQINDEX will read 0x00 and the IRQVECREG register will read the phantom interrupt address. |

15.8.5.2 FIQ Index Offset Vector Registers (FIQINDEX)

The FIQINDEX register provides the user with a numerical index value that represents the pending FIQ interrupt with the highest priority. [Figure 15-16](#) and [Table 15-8](#) describe this register.

Figure 15-16. FIQ Index Offset Vector Register (FIQINDEX) [Address = FFFF FE04h]

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 15-8. FIQ Index Offset Vector Register (FIQINDEX) Field Descriptions

| Bit | Field | Value | Description |
|------|----------|-------|--|
| 31-8 | Reserved | 0 | Read returns 0. Writes have no effect. |
| 7-0 | FIQINDEX | 0-FFh | FIQ index offset vector. The least-significant bits represent the index of the FIQ pending interrupt with the highest precedence, as shown in Table 15-6 . When no interrupts are pending, the least significant byte of FIQINDEX is 0x00. Note: A read of register FIQINDEX or FIQVECREG will cause FIQINDEX / FIQVECREG to reflect the index/ISR address for the next highest-priority pending FIQ interrupt. In case there is no other interrupt pending, the FIQINDEX will read 0x00 and the FIQVECREG register will read the phantom interrupt address. |

15.8.6 FIQ/IRQ Program Control Registers (FIRQPR[0:3])

The FIQ/IRQ program control registers (FIRQPR[0]) determine whether a given interrupt request will be either FIQ or IRQ. [Figure 15-17](#), [Figure 15-18](#), [Figure 15-19](#), [Figure 15-20](#) and [Table 15-9](#) describe these registers.

NOTE: Channel 0 and 1 are FIQ only, not impacted by this register.

Table 15-9. FIQ/IRQ Program Control Registers (FIRQPR) Field Descriptions

| Bit | Field | Value | Description |
|-------|---------------|--------|--|
| 127-2 | FIRQPR[127:2] | 0 1 | FIQ/IRQ program control bits. These bits determine whether an interrupt request from a peripheral is of type FIQ or IRQ. Bit FIRQPRx[127:2] corresponds to request channel[127:2]. Interrupt request is of IRQ type. Interrupt request is of FIQ type. |
| 1-0 | Reserved | 3h | Read only. Writes have no effect. |

15.8.7 Pending Interrupt Read Location Registers (INTREQ[0:3])

The pending interrupt register gives the pending interrupt requests. The register is updated every vbus clock cycle. [Figure 15-21](#), [Figure 15-22](#), [Figure 15-23](#), [Figure 15-24](#) and [Table 15-10](#) describe this register.

Figure 15-21. Pending Interrupt Read Location Register 0 (INTREQ0) [Address = FFFF FE20h]

LEGEND: R/W = Read/Write; W1CP = Write 1 to clear in privilege mode only; -n = value after reset

Figure 15-22. Pending Interrupt Read Location Register 1 (INTREQ1) [Address = FFFF FE24h]

LEGEND: R/W = Read/Write; W1CP = Write 1 to clear in privilege mode only; -n = value after reset

Figure 15-24. Pending Interrupt Read Location Register 3 (INTREQ3) [Address = FFFF FE2Ch]

LEGEND: R/W = Read/Write; W1CP = Write 1 to clear in privilege mode only; -n = value after reset

Table 15-10. Pending Interrupt Read Location Registers (INTREQ) Field Descriptions

| Bit | Field | Value | Description |
|-------|---------------|-------|---|
| 127-0 | INTREQ[127:0] | | Pending interrupt bits. These bits determine whether an interrupt request is pending for the request channel between 0 and 127. The interrupt ENABLE register does not affect the value of the interrupt pending bit. Bit INTREQx[127:0] corresponds to request channel[127:0]. |
| | | | User and Privilege Mode read: |
| | | 0 | No interrupt event has occurred. |
| | | 1 | An interrupt is pending. |
| | | | Privilege Mode write only: |
| | | 0 | Writing 0 has no effect. |
| | | 1 | Clears the "interrupt pending" status flag. This write-clear functionality is intended to allow clearing those interrupts which have been signaled to VIM before enabling the interrupt channel, if they are undesired. |

15.8.8 Interrupt Enable Set Registers (REQENASET[0:3])

The interrupt register enable selectively enables individual request channels. [Figure 15-25](#), [Figure 15-26](#), [Figure 15-27](#), [Figure 15-28](#) and [Table 15-11](#) describe these registers.

NOTE: Channel 0 and 1 are always enabled, not impacted by this register.

Figure 15-25. Interrupt Enable Set Register 0 (REQENASET0) [Address = FFFF FE30h]

| Bit | Field | Value | Description |
|-------|------------------|-------|--|
| 127-2 | REQENASET[127:2] | | Request enable set bits. This vector determines whether the interrupt request channel is enabled. Bit REQENASETx[127:2] corresponds to request channel[127:2]. |
| | | 0 | Read: Interrupt request channel is disabled. Write: A write of 0 has no effect. |
| | | 1 | Read or Write: The interrupt request channel is enabled. |
| 1-0 | Reserved | 3h | Read only. Writes have no effect. |

15.8.9 Interrupt Enable Clear Registers (REQENACLR[0:3])

The interrupt register enable selectively disables individual request channels. [Figure 15-29](#), [Figure 15-30](#), [Figure 15-31](#), [Figure 15-32](#) and [Table 15-12](#) describe these registers.

NOTE: Channel 0 and 1 are always enabled, not impacted by this register.

|-------|------------------|-------|--|
| 127-2 | REQENACLR[127:2] | 0 | Request enable clear bits. This vector determines whether the interrupt request channel is enabled. Bit REQENACLRx[127:2] corresponds to request channel[127:2]. Read: Interrupt request channel is disabled. Write: A write of 0 has no effect. |
| | | 1 | Read: The interrupt request channel is enabled. Write: The interrupt request channel is disabled. |
| 1-0 | Reserved | 3h | Read only. Writes have no effect. |

15.8.10 Wake-Up Enable Set Registers (WAKEENASET[0:3])

The wake-up enable registers selectively enables individual wake-up interrupt request lines. [Figure 15-33](#), [Figure 15-34](#), [Figure 15-35](#), [Figure 15-36](#) and [Table 15-13](#) describe these registers.

| Bit | Field | Value | Description |
|-------|-------------------|-------|--|
| 127-0 | WAKEENASET[127:0] | 0 | Wake-up enable set bits. This vector determines whether the wake-up interrupt line is enabled. Bit WAKEENASETx[127:0] corresponds to interrupt request channel[127:0]. Read: Interrupt request channel is disabled. Write: A write of 0 has no effect. |
| | | 1 | Read or Write: The interrupt request channel is enabled. |

15.8.11 Wake-Up Enable Clear Registers (WAKEENACLR[0:3])

The wake-up enable register selectively disables individual wake-up interrupt request lines. [Figure 15-37](#), [Figure 15-38](#), [Figure 15-39](#), [Figure 15-40](#) and [Table 15-14](#) describe these registers.

Table 15-14. Wake-Up Enable Clear Registers (WAKEENACLR) Field Descriptions

| Bit | Field | Value | Description |
|-------|-------------------|-------|--|
| 127-0 | WAKEENACLR[127:0] | 0 | Wake-up enable clear bits. This vector determines whether the wake-up interrupt line is enabled. Bit WAKEENACLRx[127:0] corresponds to interrupt request channel[127:0]. Read: Wake-up interrupt channel is disabled. Write: A write of 0 has no effect. |
| | | 1 | Read: The wake-up interrupt channel is enabled. Write: The wake-up interrupt channel is disabled. |

15.8.12 IRQ Interrupt Vector Register (IRQVECREG)

The interrupt vector register gives the address of the enabled and active IRQ interrupt. [Figure 15-41](#) and [Table 15-15](#) describe these registers.

Figure 15-41. IRQ Interrupt Vector Register (IRQVECREG) [Address = FFFF FE70h]

LEGEND: R = Read only; -n = value after reset

Table 15-15. IRQ Interrupt Vector Register (IRQVECREG) Field Descriptions

| Bit | Field | Value | Description |
|------|-----------|-----------------------------------|--|
| 31-0 | IRQVECREG | From Section 15.4 | IRQ interrupt vector register. This vector gives the address of the ISR with the highest pending IRQ request. The CPU reads the address and branches to this location. |

15.8.13 FIQ Interrupt Vector Register (FIQVECREG)

The interrupt vector register gives the address of the enabled and active FIQ interrupt. [Figure 15-42](#) and [Table 15-16](#) describe these registers.

Figure 15-42. IRQ Interrupt Vector Register (FIQVECREG) [Address = FFFF FE74h]

LEGEND: R = Read only; -n = value after reset

Table 15-16. FIQ Interrupt Vector Register (FIQVECREG) Field Descriptions

| Bit | Field | Value | Description |
|------|-----------|-----------------------------------|--|
| 31-0 | FIQVECREG | From Section 15.4 | FIQ interrupt vector register. This vector gives the address of the ISR with the highest pending FIQ request. The CPU reads the address and branches to this location. |

15.8.14 Capture Event Register (CAPEVT)

Figure 15-43 and Table 15-17 describe this register.

Figure 15-43. Capture Event Register (CAPEVT) [Address = FFFF FE78h]

Table 15-17. Capture Event Register (CAPEVT) Field Descriptions

| Bit | Field | Value | Description |
|-------|------------|---------------------|--|
| 31-23 | Reserved | 0 | Reads are indeterminate and writes have no effect. |
| 22-16 | CAPEVTSRC1 | 0 1h : 7Fh | Capture event source 1 mapping control. These bits determine which interrupt request maps to the capture event source 1 of the RTI: Interrupt request 0. Interrupt request 1. : Interrupt request 127. |
| 15-7 | Reserved | 0 | Reads are indeterminate and writes have no effect. |
| 6-0 | CAPEVTSRC0 | 0 1h : 7Fh | Capture event source 0 mapping control. These bits determine which interrupt request maps to the capture event source 0 of the RTI: Interrupt request 0. Interrupt request 1. : Interrupt request 127. |

15.8.15 VIM Interrupt Control Registers (CHANCTRL[0:31])

Thirty-two interrupt control registers control the 128 interrupt channels of the VIM. Each register controls four interrupt channels: each of them is indexed from 0 to 127. [Table 15-18](#) shows the organization of all the registers and the reset value of each. Each four fields of the register has been named with a generic index that refers to the detailed register organization. [Figure 15-44](#) and [Table 15-19](#) describe these registers.

Table 15-18. Interrupt Control Registers Organization

| Address | Register Acronym | Register Field 31:24 CHANMAP _{x0} | Register Field 23:16 CHANMAP _{x1} | Register Field 15:8 CHANMAP _{x2} | Register Field 7:0 CHANMAP _{x3} | Reset Value |
|-------------|------------------|---|---|--|---|-------------|
| FFFF FE80h | CHANCTRL0 | CHANMAP0 | CHANMAP1 | CHANMAP2 | CHANMAP3 | 0001 0203h |
| FFFF FE84h | CHANCTRL1 | CHANMAP4 | CHANMAP5 | CHANMAP6 | CHANMAP7 | 0405 0607h |
| : | : | : | : | : | : | : |
| FFFF FEF8h | CHANCTRL30 | CHANMAP120 | CHANMAP121 | CHANMAP122 | CHANMAP123 | 7879 7A7Bh |
| FFFF FEFCCh | CHANCTRL31 | CHANMAP124 | CHANMAP125 | CHANMAP126 | CHANMAP127 | 7C7D 7E7Fh |

NOTE: CHANMAP0 and CHANMAP1 are not programmable. CHAN0 and CHAN1 are hard wired to INT_REQ0 and INT_REQ1.

Do NOT write any value other than 0x7F to CHANMAP127. Channel 127 is reserved because no interrupt vector table entry supports this channel.

| | | 7Fh | Read: Interrupt request 127 maps to channel priority CHANx ₃ . Write: The default value of this bit after reset is given in Table 15-18 . The channel priority CHANx ₃ is set with the interrupt request. |

Direct Memory Access Controller (DMA) Module

This chapter describes the direct memory access (DMA) controller.

| Topic | Page |
|---|-------------|
| 16.1 Overview | 564 |
| 16.2 Module Operation | 565 |
| 16.3 Control Registers and Control Packets | 583 |

16.1 Overview

The DMA controller is used to transfer data between two locations in the memory map in the background of CPU operations. Typically, the DMA is used to:

- Transfer blocks of data between external and internal data memories
- Restructure portions of internal data memory
- Continually service a peripheral
- Page program sections to internal program memory

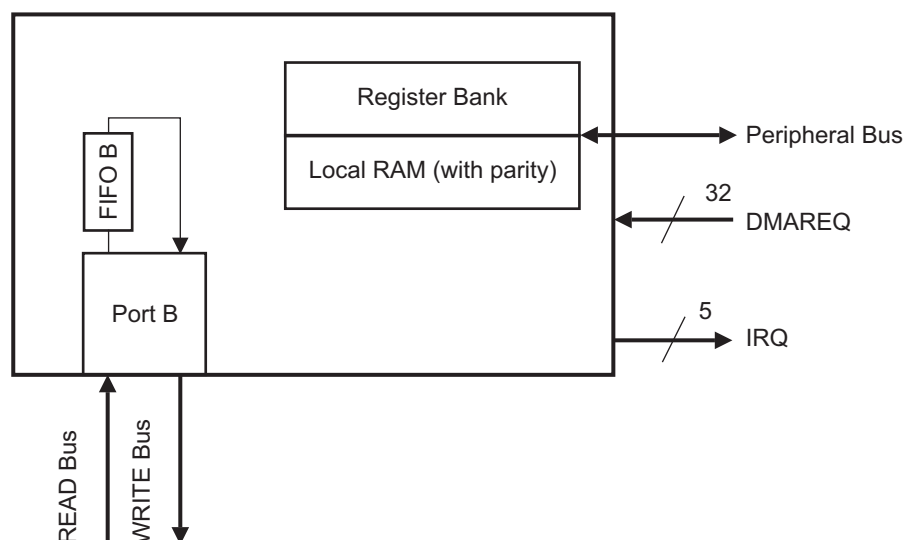

16.1.1 Main Features

- CPU independent data transfer
- One master port - PortB (64-bits wide) that interfaces microcontrollers Memory System.
- FIFO buffer (4 entries deep and each 64-bits wide)
- Channel control information is stored in RAM protected by parity
- 16 channels with individual enable
- Channel chaining capability
- 32 peripheral DMA requests
- Hardware and Software DMA requests
- 8, 16, 32 or 64-bit transactions supported
- Multiple addressing modes for source/destination (fixed, increment, offset)
- Auto-initiation
- Power-management mode
- Memory Protection for the address range DMA can access with four configurable memory regions

16.1.1.1 Block Diagram

Figure 16-1 gives a detailed view of the DMA internal architecture. DMA data read and write access happens through Port B. FIFO B is 4 levels deep and 64-bits wide. 32 DMA requests go into the DMA that can trigger DMA transfers. Five interrupt request lines go out of the DMA to signal that a certain transfer status is reached. Register banks hold the memory mapped DMA configuration registers. Local RAM consists of DMA control packets and is secured by parity. All the programming / configuration of the DMA controller is done via the Peripheral bus.

Figure 16-1. DMA Block Diagram

16.2 Module Operation

The DMA acts as an independent master in the platform architecture. All DMA memory and register accesses are performed in user mode. If the DMA writes to registers that are only accessible in privileged mode, the write will not be performed.

The DMA registers and its local RAM can only be accessed in privilege mode. Therefore, it is not possible for the DMA to reprogram itself.

16.2.1 Memory Space

The DMA controller makes no distinction between program memory and data memory. The DMA controller can transfer to and from any space within the 4 gigabyte physical address map, by programming the absolute address for the source and destination in the control packet. Control packets store the transfer information such as source address, destination address, transfer count and control attributes for each channel.

16.2.2 DMA Data Access

The DMA controller refers to data in three levels of granularity:

- **Element:** Depending on the programmed data type, an 8-bit, 16-bit, 32-bit, or a 64-bit value. The type can be individually selected for the source (read) and destination (write). See [Figure 16-2](#) and [Figure 16-3](#) for an example of the use of elements. An element transfer cannot be interrupted.
- **Frame:** One or more elements to be transferred as a unit. A frame transfer can be interrupted between element transfers. See [Figure 16-2](#) for an example.
- **Block:** One or more frames to be transferred as a unit. Each channel can transfer one block of data (once or multiple times). See [Figure 16-3](#) for an example.

Figure 16-2. Example of a DMA Transfer Using Frame Trigger Source

Figure 16-3. Example of a DMA Transfer Using Block Trigger Source

16.2.3 Addressing Modes

There are three addressing modes supported by the DMA controller that can be setup independent for the source and the destination address:

- Constant -- source and/or destination addresses do not change.
- Post incremented -- source and/or destination address are post-incremented by the element size.
- Indexed -- source and/or destination address is post-incremented as defined in the Element Index Offset Register ([Section 16.3.2.5](#)) and the Frame Index Offset Register ([Section 16.3.2.6](#)).

An unaligned address with respect to the element size is not supported.

16.2.4 DMA Channel Control Packets

There are a total of 16 control packets. Each control packet is associated with a channel in a fixed order. For example, control packet 0 stores channel information for channel 0. The DMA requests can be mapped to the individual channels as described in [Section 16.2.7](#). The mapping scheme between DMA requests and channels is shown in [Figure 16-4](#). Each control packet contains nine fields. The first six fields compose the primary control packet and are programmable during DMA setup. The last three fields compose working control packet and are only readable by the CPU. The working control packets are used to support auto-initiation. The organization of control packets is shown in [Figure 16-5](#).

The primary control packet contains channel information such as source address, destination address, transfer count, element/frame index pointer and channel configuration. Source address, destination address and transfer count also have their respective working images. The three fields of working images compose a working control packet and are not accessible to the CPU in write access.

The first time a DMA channel is selected for a transaction, the following process occurs:

1. The primary control packet is first read by the DMA state machine.
2. Once the channel is arbitrated, the current source address, destination address and transfer count are then copied to their respective working images.
3. When the channel is serviced again by the DMA, the state machine will read both the primary control packet and the working control packet to continue the DMA transaction until the end of an entire block transfer.

When the same channel is requested again, the state machine will start again by reading only the primary control packet and then continue the same process described above. The user software need not set up control packets again because the contents of the primary control packet were never lost. The working images of the control packets are reducing the software overhead and interaction with the DMA module to a minimum.

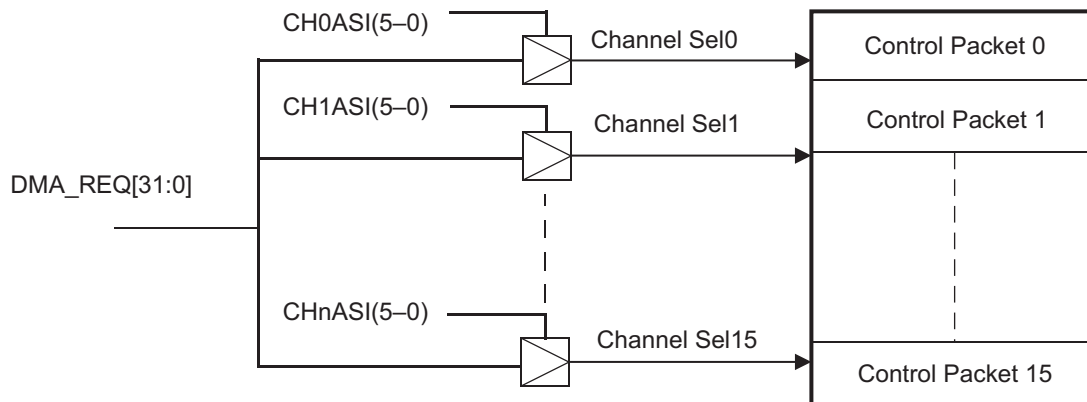

NOTE: Changing the contents of a channel control packet will clear the corresponding pending bit ([Section 16.3.1.2](#)) if the channel has a pending status. If the control packet of an active channel (as indicated in [Section 16.3.1.3](#)) is changed, then the channel will stop immediately at an arbitration boundary. When the same channel is triggered again, it will begin with the new control packet information.

16.2.4.1 Initial Source Address

This field stores the absolute 32-bit source address of the DMA transfer.

16.2.4.2 Initial Destination Address

This field stores the absolute 32-bit destination address of the DMA transfer.

16.2.4.3 Initial Transfer Count

The transfer count field is composed of two parts. The frame transfer count value and the element transfer count value. Each count value is 13 bits wide. As a Single Block transfer maximum of 512 Mbytes of data can be transferred. Element count and frame count are programmed according to the source data structure.

The total transfer size is calculated as:

$$T_{sz} = E_{rsz} \cdot E_{tc} \cdot F_{tc} \quad (27)$$

where

T_{sz} = Total Transfer Size

E_{rsz} = Read Element Size

E_{tc} = Element Transfer Count

F_{tc} = Frame Transfer Count

NOTE: A zero element count with a non-zero frame count or a non-zero element count with a zero frame count are all considered as zero total transfer count. No DMA transaction is initiated with any of the counters set to 0.

16.2.4.4 Channel Configuration Word

The channel configuration defines the following individual parameters

- Read element size
- Write element size
- Trigger type (frame or block)
- Addressing mode for source
- Addressing mode for destination
- Auto-initiation mode
- Next control packet to be triggered at control packet finish (Channel Chaining)

16.2.4.5 Element/Frame Index Pointer

There are 4 index pointers that allow the creation of different types of buffers in RAM and address registers in a structured manner: an element index pointer for source and destination and a frame index pointer for source and destination.

The element index pointer for source and/or destination defines the offset to be added after each element transfer to the source and/or destination address. The frame index pointer for source and/or destination defines the offset to be added to the source and/or destination address after the element count reaches zero. The element and frame index pointers must be defined in terms of the number of bytes of offset. The DMA controller does not adjust the element/frame index number according to the element size. An index of 2 means *increment the address by 2* and not by 16 when the element size is 64 bits.

16.2.4.6 Current Source Address

The current source address field contains the current working source address during a DMA transaction. The current source address is incremented during post increment addressing mode or indexing mode.

16.2.4.7 Current Destination Address

The current destination address field contains the current working destination address during a DMA transaction. The current destination address is incremented during post-increment addressing mode or indexing mode.

16.2.4.8 Current Transfer Count

The current transfer count stores the remaining number of elements to be transferred in a block. It is decremented by one for each element read from the source location.

Figure 16-6, Figure 16-7, and Figure 16-8 show some examples of DMA transfers.

Figure 16-6. DMA Transfer Example 1

| Source | | | | Destination | | | |
|---------------------------|----|----|----|-------------|-----|----------|----------|
| | f1 | f2 | f3 | f4 | | | |
| 0x00 | E1 | E3 | E5 | E7 | 0x0 | E1/3/5/7 | E2/4/6/8 |
| 0x04 | | | | | 0x4 | | |

| 0x80 | E3 | E6 | E9 | E12 | E15 | E18 | E21 | E23 |

Element Index = 64

Frame Index = 4

This example can be applied to either source or destination indexing and assumes the following setup.

Element Size = 32 bit

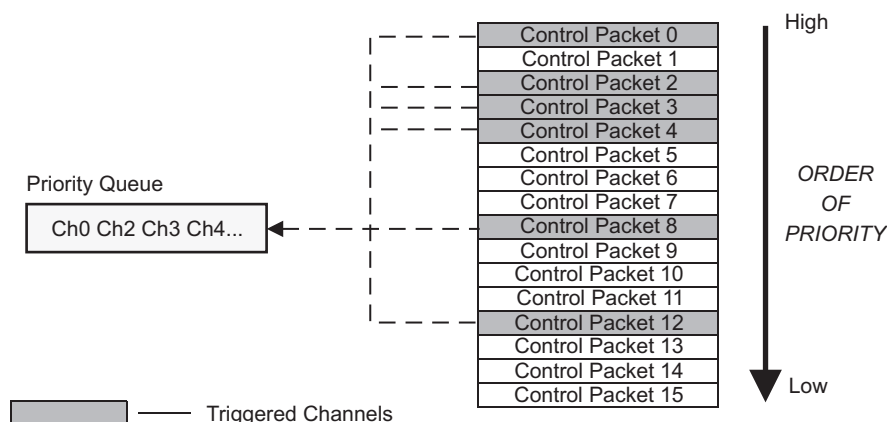

Element Count = 3

Frame Count = 8

16.2.5 Priority Queue

User can assign channels in to priority queues to facilitate request handling during arbitration. The port has two priority queues: a high and a low priority queue. The queue can be configured to follow a fixed or rotating priority scheme. Fixed priority is such that the lower the channel number (Figure 16-9), the higher its priority. Rotating priority is based on a round-robin scheme. Initially, the priority list is sorted according to the fixed priority scheme. Channels assigned to the high priority queue are always serviced first according to the selected priority scheme before channels in the low priority queue are serviced. Table 16-1 describes how arbitration is performed according to different priority schemes.

NOTE: Since the DMA controller provides the capability to map any one of the 32 hardware DMA request lines to any channel, the numerical order of the hardware DMA request does not imply any priority. The priority of each hardware DMA request is programmed and determined by software.

Figure 16-9. Fixed Priority Scheme

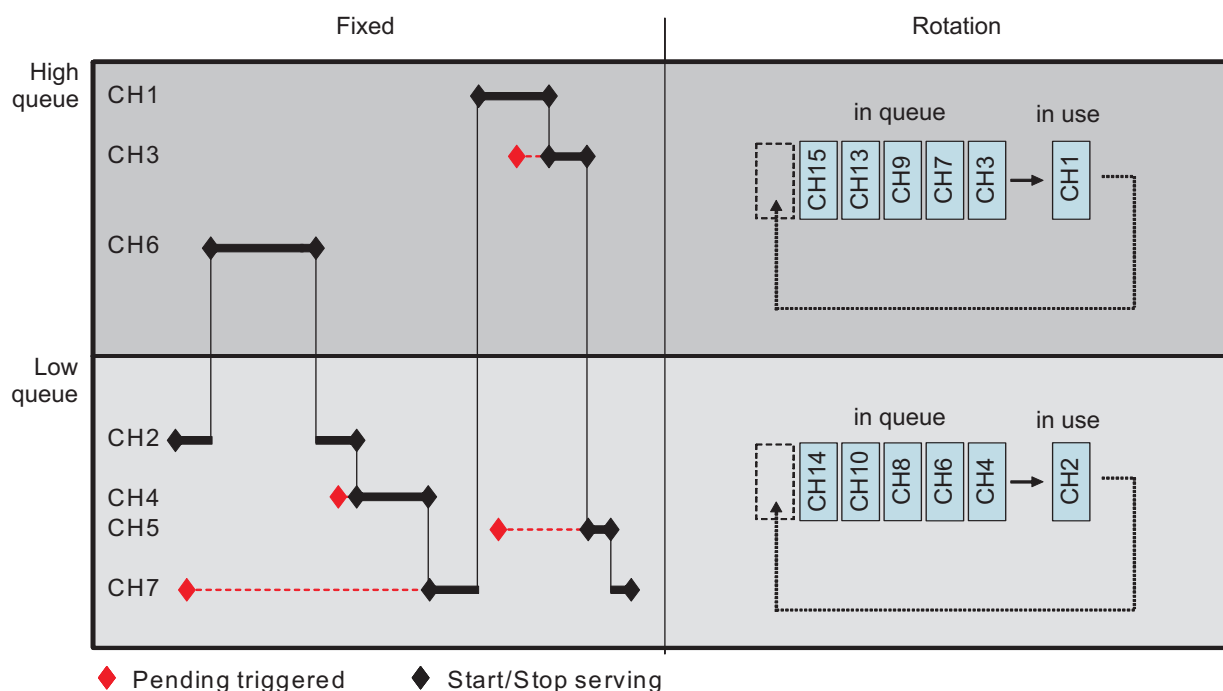

The above figure illustrates that by default Lower the channel number, higher the Priority.

Table 16-1. Arbitration According to Priority Queues and Priority Schemes

| Queue | Priority Scheme | Remark |
|---------------|-----------------|--|
| High priority | Fixed | Channels are serviced in an ascending order according to the channel number. The lower the channel number, the higher the priority. A channel will be arbitrated out whenever there is a higher pending channel. Otherwise a channel is completely serviced until its transfer count reaches zero before the next highest pending channel is serviced. When there is no pending channels left in high queue then the DMA switches to service low queue channels. |
| | Rotating | Channels are arbitrated by using the round-robin scheme. Arbitration is performed when the FIFO is empty. When there are no pending channels left in high queue then the DMA switches to service low queue channels. |
| Low priority | Fixed | Channels are serviced in an ascending order according to the channel number. The lower the channel number the higher the priority. A channel will be arbitrated out whenever there is a higher-priority pending channel. Otherwise a channel is completely serviced until its transfer count reaches zero, before the next highest pending channel is serviced. If there is a pending channel in the high-priority queue while DMA is servicing a low queue channel then DMA will switch back to service high queue channel after an arbitration boundary. |
| | Rotating | Channels are arbitrated by using round-robin scheme. Arbitration is performed when the FIFO is empty. |

A Simple Priority Queues example in both Fixed and Rotation Scheme is shown in [Figure 16-10](#).

Figure 16-10. Example of Priority Queues

For optimal system performance, the high priority channels should be put in fixed arbitration scheme and low priority channels in the rotating priority scheme as illustrated in [Figure 16-11](#).

Figure 16-11. Example Channel Assignments

1 The above figure illustrates the channel assignments in a system with 16 channels. This approach can be scaled dependent on the total channels available.

16.2.6 Data Packing and Unpacking

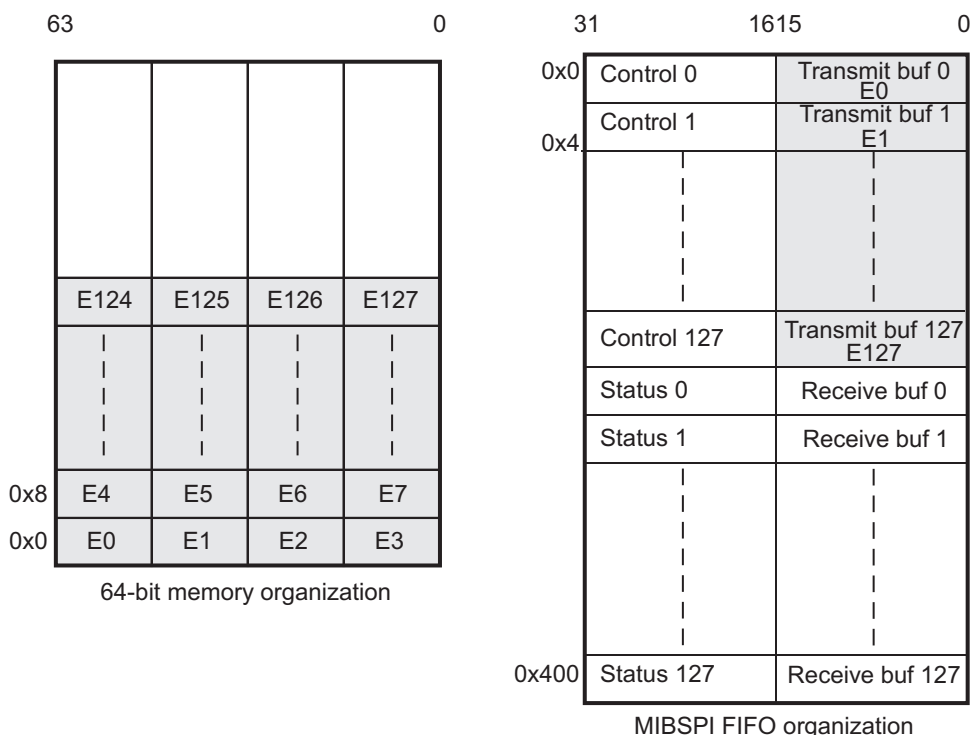

The DMA controller automatically performs the necessary data packing and unpacking when the read element size differs from the write element size. Data packing is required when the read element size is smaller than the write element size; data unpacking is required when the read element size is larger than the write element size. When the read element size is equal to the write element size, no packing is performed during read, nor is any unpacking performed during write.

[Figure 16-12](#) shows an example of data unpacking in which the DMA is used to transfer 128 transmit data elements to the MibSPI FIFO buffer. In this example, data unpacking is required because the read element size is 64 while the write element size is 16. The DMA first performs a 64-bit read from the source into its FIFO buffer. After the 64-bit data is read into the DMA FIFO buffer, it must unpack the data into four 16-bit data elements before writing out to the destination. Therefore the DMA would need to perform four 16-bit write operations to the destination.

NOTE: In the example in [Figure 16-12](#), to transmit data at the lower bits of the MibSPI, bits 15:0, the destination address should be incremented by a factor of 2.

- NOTE:**
- 1) The element Count ([Section 16.3.2.3](#)) refers only to the read element.
 - 2) Data unpacking does not require the DMA request. Once the DMA request is received, data from Source is moved in to FIFO and unpacking happens until the FIFO is empty.
 - 3) DMA assumes the destination is always ready and will perform write immediately. In case of data unpacking and Constant Addressing Mode write ([Section 16.3.2.4](#) (1 - 0) = 0) the destination data will be overwritten by next data or next data might be skipped in case the destination has overflow protection (eg., SCITD register). User should configure DMA to avoid data unpacking if the Destination is configured as Constant Addressing Mode write to avoid data loss.

Figure 16-12. Example of DMA Data Unpacking

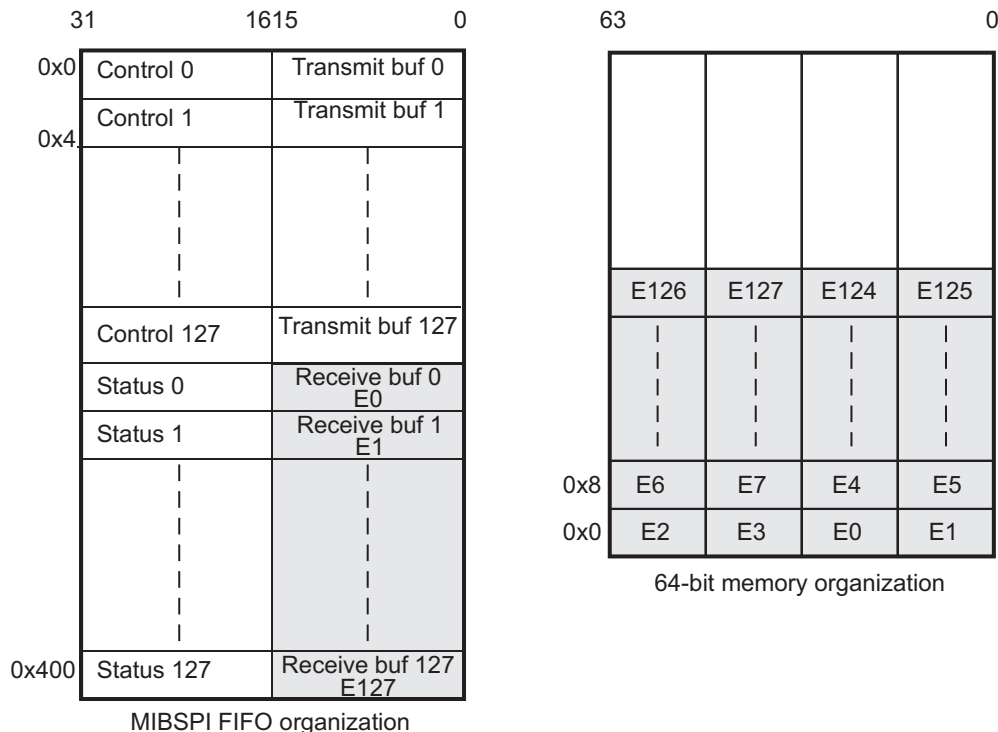

In this example, initialization of the MIBSPI FIFO is illustrated and assumes the following setup:

Read Element Size = 64 bit
 Write Element Size = 16 bit
 Element Count = 32
 Frame Count = 1
 Source Element Index = n/a, use post increment addressing mode
 Source Frame Index = n/a, use post increment addressing mode
 Destination Element Index = 4
 Destination Frame Index = 0

When the read element size is smaller than the write element size, the DMA controller needs to perform data packing. The number of elements to pack is equal to the ratio between the write element size and read element size. In the example in [Figure 16-13](#), the read element size is 16 bits and the write element size is 64 bits. The DMA controller would first pack the first four elements by performing four consecutive 16-bit read accesses of E0, E1, E2, and E3 into the first word of the DMA's internal FIFO. The DMA controller would then perform one single 64-bit write operation to transfer the data to the 64-bit destination memory.

Normally, the DMA controller carries out bus transactions on the bus according to the element size. For example, the DMA controller would perform a 16-bit read transaction if the read element size is programmed as 16 bits, or an 8-bit write transaction if the write element size is programmed as 8 bit. The exception is when the total transfer size is as defined in [Equation 27](#) is not a multiple of the write element size.

Figure 16-13. Example of DMA Data Packing

In this example, a read of the MIBSPI FIFO is illustrated and assumes the following setup:

Read Element Size = 16 bit
 Write Element Size = 64 bit
 Element Count = 128
 Frame Count = 1
 Source Element Index = 4
 Source Frame Index = 0
 Destination Element Index = n/a, use post increment addressing mode
 Destination Frame Index = n/a, use post increment addressing mode

For example, if the read element size is 8 bits, the element transfer count is equal to 9, and the write element size is 64 bit. The DMA controller would first perform eight 8-bit read transactions from the source. It would then perform a 64-bit write to the destination. When the same channel wins arbitration again, the DMA controller would first perform one 8-bit read from the source, followed by one 8-bit write to the destination, even though the write element size is 64 bit.

NOTE: Since peripherals are slower, it is advised to use data packing feature with caution for reading data from peripherals. Improper use might delay servicing other pending DMA channels.

16.2.7 DMA Request

There are three ways to start a DMA transfer:

- **Software request:** The transfer will be triggered by writing to SW Channel Enable Set and Status Register (Section 16.3.1.6). The software request can trigger either a block or a frame transfer depending on what the trigger type (TTYPE) bit is set to in the Channel Control Register (Section 16.3.2.4).
- **Hardware request:** The DMA controller can handle up to 32 DMA Request lines. A hardware request can trigger either a frame or a block transfer dependent on the setting of TTYPE control bit of the Channel Control Register (Section 16.3.2.4).
- **Triggered by other control packet:** When a control packet finishes the programmed number of transfers it can trigger another channel to initiate its transfers.

Each time a DMA request is made, either one frame transfer or one block transfer can be chosen. An active DMA request signal will trigger a DMA transaction.

The DMA controller has a two-level buffer to capture HW requests per channel. When a HW request is generated and the channel is enabled, the corresponding bit in the DMA Status Register (Section 16.3.1.3) is set. The pending register acts as a first-level buffer. Typically, a peripheral acting as a source of a transfer would initiate another request after its data registers have been read out by DMA, even though that data has not been completely transferred to the destination. If a second HW request is generated by the peripheral, the DMA controller has an extra request buffer to capture this second request and service it after the first request is complete.

NOTE: The DMA cannot capture more than three requests if its request buffers are already full. If any request occur during this moment DMA will discard it.

The DMA controller also supports a mix of hardware and software requests on the same channel. Note that such interchangeable usage may result into an out of sync for DMA channel and peripheral. The application needs to be careful as the DMA does not have a built-in mechanism to protect against this loss of synchronization.

If a software request is generated, the corresponding bit in the Channel Pending Register (Section 16.3.1.2) is set accordingly. If the pending request is not completely serviced by the DMA and a hardware request is generated by a peripheral onto the same channel, the DMA will capture and recognize this hardware request into its request buffer.

NOTE: The DMA controller cannot recognize two software requests on the same channel if the first software request is still pending. If such request occur DMA will discard it. Therefore the user software should check the pending register before issuing a new software request.

16.2.8 Auto-Initiation

When Auto-initiation Mode (AIM) bit of Channel Control Register (Section 16.3.2.4) is enabled for a channel and the channel is triggered by a software request for a block transfer, the channel will restart again using the same channel information stored at the respective control packet after one block transfer is completed. In the case of Hardware Request, the channel needs to be retriggered each time after a block is complete even if auto-initiation is enabled.

16.2.9 Interrupts

Each channel can be configured to generate interrupts on several transfer conditions:

- Frame transfer complete (FTC) interrupt: an interrupt is issued after the last element of a frame has been transferred.
- Last frame transfer started (LFS) interrupt: an interrupt is issued before the first element of the last frame of a block transfer has started.
- First half of block complete (HBC) interrupt: an interrupt is issued if more than half of the block is transferred.
 - If the number of frames n is odd, then the HBC interrupt is generated at the end of the frame when $(n+1)/2$ number of frames are left in the block.
 - If the number of frames n is even, then the HBC interrupt is generated at the end of the frame after $n/2$ number of frames are left in the block.
- Block transfer complete (BTC) interrupt: an interrupt is issued after the last element of the last frame has been transferred.
- External imprecise error on read: an interrupt can be issued when a bus error (Illegal transaction with ok response) is detected. The imprecise read error is connected to the ESM module.
- External imprecise error on write: an interrupt can be issued when a bus error (Illegal transaction with ok response) is detected. The imprecise write error is connected to the ESM module.
- Memory Protection Unit error (MPU): an interrupt is issued when the DMA detects that the access falls outside of a memory region programmed in the MPU registers of the DMA. The MPU interrupt is connected to the ESM module.
- Parity error (PAR): an interrupt is issued when the DMA detects a parity error when reading one of the control packets. The PAR interrupt is connected to the ESM module.

The DMA outputs 5 interrupt lines for control packet handling, a parity interrupt and a memory protection interrupt (Figure 16-14). Each type of transfer interrupt condition is grouped together. For example, all block-transfer complete interrupts that are routed to a port are combined (ORed). The channel that caused the interrupt is given in the corresponding interrupt channel offset register. Priority between interrupts among the same interrupt type is resolved by a fixed priority scheme. Priority between different interrupt types is resolved in the Vector Interrupt Manager. Figure 16-15 explains the Frame Transfer Complete Interrupt structure in detail.

NOTE: Each Channel Specific interrupts in DMA module are routed towards Group A or B to support two different CPUs individually. For devices with Single CPU or Dual CPU where both CPUs are running same code in delayed lock-step as safety feature:

Group A - Interrupts (FTC, LFS, HBC, and BTC) are routed to the ARM CPU.

Group B - Interrupts (FTC, LFS, HBC, and BTC) are not routed out.

User software should configure only Group A interrupts.

Figure 16-14. DMA Interrupts

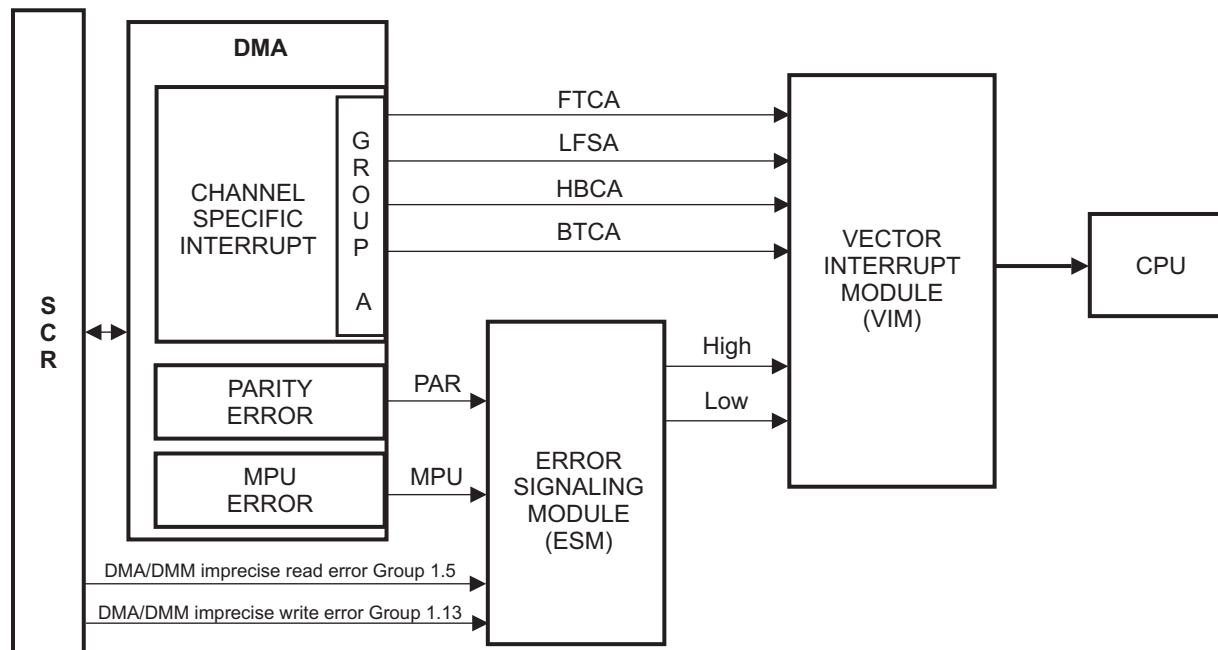

Figure 16-15. Detailed Interrupt Structure (Frame Transfer Complete Path)

This figure is applicable for the HBC, LFS, and BTC interrupt.

16.2.10 Debugging

The DMA supports four different behaviors in suspend mode. These behaviors can be configured by the user as per the application requirement.

- Immediate stop at a DMA channel arbitration boundary. Please refer to [Table 16-2](#) and [Table 16-3](#) for arbitration boundary definition.
- Finish current frame transfer and continue after suspend ends.
- Finish current block transfer and continue after suspend ends.
- Ignore the suspend. The DMA continues to be operational as in functional mode when debug mode is active.

When the DMA controller enters suspend mode, it continues to sample incoming hardware DMA requests, but the Channel Pending Register ([Section 16.3.1.2](#)) is frozen from being updated. After the suspend ends, all new requests that were received during suspend mode are reflected in the Channel Pending Register ([Section 16.3.1.2](#)).

Except when the DMA controller is configured to ignore suspend mode, no channel arbitration is performed during suspend mode. The current channel under which suspend mode was entered will finish its entire frame or block-transfer after suspend mode ends, depending how the debug option was chosen.

To facilitate debugging, a Watch Point Register ([Section 16.3.1.47](#)) and a Watch Mask Register ([Section 16.3.1.48](#)) are used. The watch point register together with the watch mask register can be configured to watch for a unique address or a range of addresses. When the condition to watch is true, the DMA freezes its state and generates a debug request signal to the host CPU so the state of the DMA can be examined.

16.2.11 Power Management

The DMA offers two power-management modes: run and sleep. In run mode, the DMA is fully operational.

The sleep mode shuts down the DMA if no pending channels are waiting to be serviced. If a DMA request is received or a software request is generated by the user software, then the DMA wakes up immediately.

The sleep mode may be used to optimize the DMA module power consumption.

When the system module issues a global low power mode request, the DMA will respond to the system module with an acknowledge if no DMA requests are pending.

NOTE: When the DMA is in global low power mode, the clock is stopped and therefore it cannot detect any DMA request. The device must be woken up before a peripheral can generate a DMA request.

16.2.12 FIFO Buffer

DMA FIFO is 4 levels deep and 64-bit wide (can hold up to 4 x 64-bits of data). They are used for Data packing and unpacking.

The DMA FIFO has two states:

- **EMPTY** : The FIFO contains no data.
- **FULL** : The FIFO is filled or the element count has reached zero; the read operation has to be stopped.

DMA channels can only be switched when the FIFO is empty. This also implies that arbitration between channels is done when the FIFO is empty.

The FIFO buffer may be bypassed through the use of the bypass feature in the port control register; see Port Control Register ([Section 16.3.1.44](#)) for register details. Writing 1 to this bit limits the FIFO depth to the size of one element. That means after one element is read the write out to the destination will start. This feature is particularly useful to minimize switching latency in-between channels. When bypass mode is enabled, the DMA will perform minimal bus cycles on AHB bus. In addition, the bypass feature allows arbitration between channels that can be carried out at a source element granularity.

However, it has to be considered that while in bypass mode, the DMA controller does not make optimal use of the bus bandwidth. Since the read and write element sizes can be different, then the number of read and write transactions will be different. [Table 16-2](#) and [Table 16-3](#) show a comparison between the number of read and write transactions performed by the DMA controller from one channel to another before arbitration in non-bypass and bypass mode.

Table 16-2. Maximum Number of DMA Transactions per Channel in Non-Bypass Mode

| | Write Element Size | 8 bit | | 16 bit | | 32 bit | | 64 bit | |
|-------------------|--------------------|--------|---------|--------|---------|--------|---------|--------|---------|
| Read Element Size | 8 bit | 4 read | 4 write | 4 read | 2 write | 4 read | 1 write | 8 read | 1 write |
| | 16 bit | 2 read | 4 write | 4 read | 4 write | 4 read | 2 write | 4 read | 1 write |
| | 32 bit | 1 read | 4 write | 2 read | 4 write | 4 read | 4 write | 4 read | 2 write |
| | 64 bit | 1 read | 8 write | 1 read | 4 write | 2 read | 4 write | 4 read | 4 write |

Table 16-3. Maximum Number of DMA Transactions per Channel in Bypass Mode

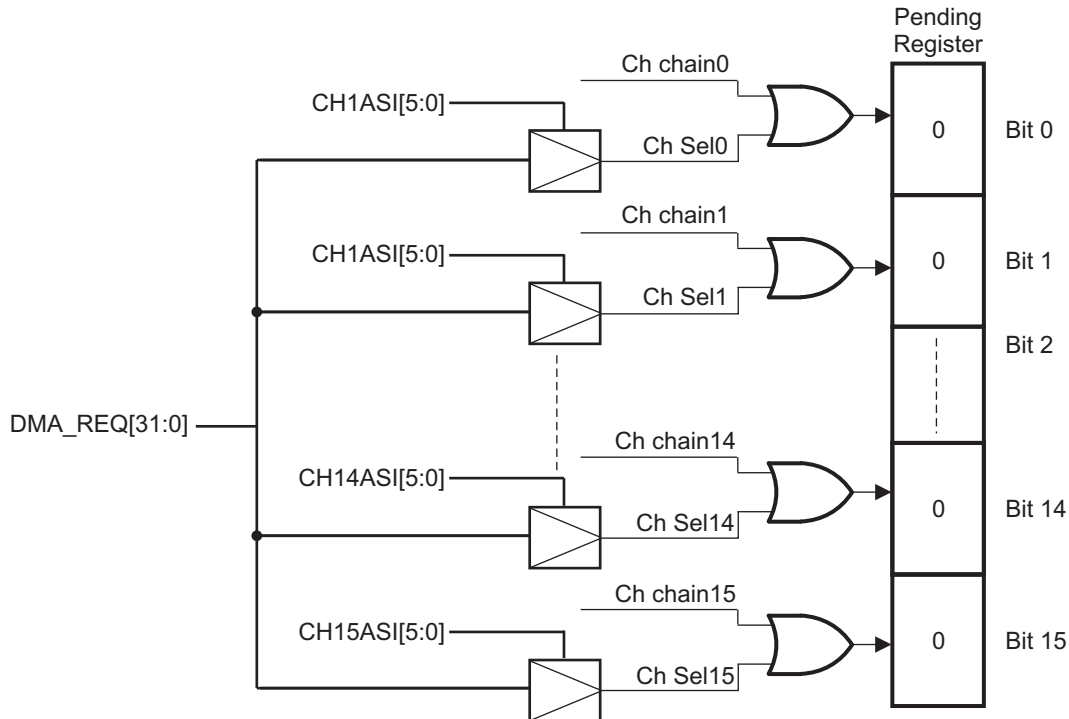

| | Write Element Size | 8 bit | | 16 bit | | 32 bit | | 64 bit | |
|-------------------|--------------------|--------|---------|--------|---------|--------|---------|--------|---------|
| Read Element Size | 8 bit | 1 read | 1 write | 2 read | 1 write | 4 read | 1 write | 8 read | 1 write |
| | 16 bit | 1 read | 2 write | 1 read | 1 write | 2 read | 1 write | 4 read | 1 write |
| | 32 bit | 1 read | 4 write | 1 read | 2 write | 1 read | 1 write | 2 read | 1 write |
| | 64 bit | 1 read | 8 write | 1 read | 4 write | 1 read | 2 write | 1 read | 1 write |

16.2.13 Channel Chaining

Channel chaining is used to trigger a single or multiple channels with out an external DMA request. This is possible by chaining one control packet to other. Chain[5:0] field of the Channel Control Register ([Section 16.3.2.4](#)) is used to program the chaining control packet. Chained control packets follow arbitration rules within the pending register. For example if CH1, CH2, CH4, CH5 are triggered together and CH3 is chained with CH1. The order of channels serviced in spite of chaining will be CH1 -> CH2 -> CH3 -> CH4 -> CH5.

In order to setup up channel chain feature, the Channel Control Register ([Section 16.3.2.4](#)) needs to be enabled for all chained channels before triggering first DMA request.

[Figure 16-16](#) illustrates how internally chained request is generated after completing the required transfers and stored in pending register. In this example CH1 is Chained to CH0. When CH0 is triggered CH1 is captured as pending in the Channel Pending Register ([Section 16.3.1.2](#)) even when it is not triggered.

Figure 16-16. Example of Channel Chaining

16.2.14 Memory Protection

The DMA controller is capable of access to the full address range of the device. The protection mechanism allows the protection of up to four memory regions to restrict accesses to those address ranges. This will allow the application to protect critical application data from unintentionally being accessed by the DMA controller.

16.2.14.1 Protection Mechanism

The memory protection mechanism consists of the access privilege for a given memory region, the start and end address for the region, and notification of an access violation for the protected region.

Each region to be protected is configured by software by writing the start address and end address for each region into the DMA Memory Protection Registers, DMAMPRxS and DMAMPRxE. The definition of these registers can be found starting at [Section 16.3.1.54](#). Any region in the valid address space can be protected from inappropriate accesses.

The access privileges can be set to one of four permission settings as shown below:

- Full access
- Read only access
- Write only access
- No access

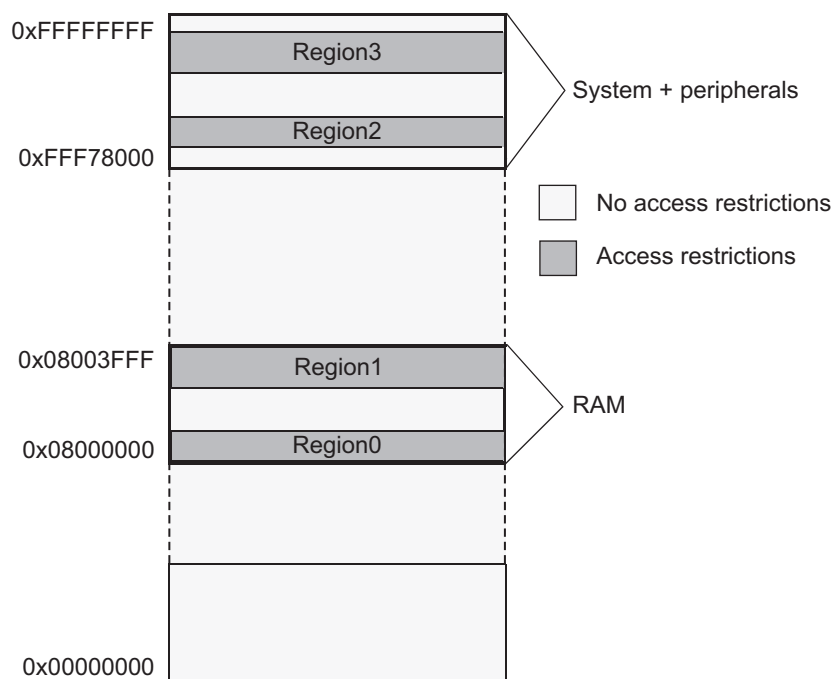

The permissions for a given region are selected by writing the appropriate values in the DMA Memory Protection Control Register ([Section 16.3.1.54](#)).

NOTE: If the regions defined by the start and end addresses overlap, the region defined first in the register space determines the access privilege. For example, if region 0 and region 1 overlap, the access permissions defined for region 0 will take precedence since region 0 registers are before region 1.

In a case where a memory protection violation occurs, a flag will be set and an interrupt will be generated, if interrupts are enabled. The DMA Memory Protection Status Register ([Section 16.3.1.55](#)) contains the status flags for the memory protection mechanism, and the DMA Memory Protection Control Register ([Section 16.3.1.54](#)) contains the interrupt enable bits. Upon detection of the memory protection violation, the DMA Channel that caused the violation will be stopped and the next available DMA channel will be serviced.

Figure 16-17 illustrates a protection mechanism.

Figure 16-17. Example of Protection Mechanism

16.2.15 Parity Checking

Parity checking is implemented using parity on a per-byte basis for DMA Control Packets in the RAM. Checking for even or odd parity can be programmed by a 4-bit key located in the system module that controls the parity configuration on a global basis. This ensures that all modules using parity are acting in the same manner. The default setup after reset is odd parity.

In addition, parity checking can be enabled and disabled within the module by a 4-bit key. The key is located in the Parity Control Register ([Section 16.3.1.52](#)).

During a read access, regardless if it was read by the DMA state machine or another master (CPU), the parity is calculated based on the data read from the RAM and compared with the good parity value stored in the parity bits. If any word fails the parity check, then a parity error interrupt is generated. The address that generated the error is detected and is captured for host system debugging in the DMA Parity Error Address Register ([Section 16.3.1.53](#)). The address is frozen from being updated until it is read by the bus master.

Additional error handling is dependent on the requestor.

- DMA reading from a control packet RAM: The transmission requested by DMA request will not take place.
- CPU reading from the control packet RAM: The data will be retrieved by the CPU and a parity error interrupt will be generated.

In both cases, the control packet will be left active or the DMA will be switched off dependent on the ERRA bit in the Parity Control Register ([Section 16.3.1.52](#)).

16.2.16 Parity Testing

The parity RAM is accessible to allow manually inserting faults so that the parity checking feature can be tested. Test mode is entered by asserting the TEST bit in the Parity Control Register ([Section 16.3.1.52](#)). Once the bit is set, the parity bits are mapped to the control packet RAM starting address A00h.

NOTE: When in test mode, no parity checking will be done when reading from parity memory, but parity checking will be performed on the normal memory.

Each byte in Control Packet RAM has its own parity bit in the Control Packet Parity RAM as shown in [Table 16-4](#), [Table 16-5](#), and [Table 16-6](#). P0 is the parity bit for byte 0, P1 is the parity bit for byte 1 and so on.

Each byte in the control packet RAM has its own parity bit in the control packet parity RAM as shown in [Table 16-4](#) and [Table 16-5](#).

Table 16-4. Control Packet RAM

| Bit | 31 | 24 | 23 | 16 | 15 | 8 | 7 | 0 |
|-------|---------|----|---------|----|---------|---|---------|---|
| Word0 | Byte 0 | | Byte 1 | | Byte 2 | | Byte 3 | |
| Word1 | Byte 4 | | Byte 5 | | Byte 6 | | Byte 7 | |
| Word2 | Byte 8 | | Byte 9 | | Byte 10 | | Byte 11 | |
| Word3 | Byte 12 | | Byte 13 | | Byte 14 | | Byte 15 | |

| | P15 | P14 | P13 | P12 | P11 | P10 | P9 | P8 | P7 | P6 | P5 | P4 | P3 | P2 | P1 | P0 |

16.2.17 Initializing RAM with Parity

After power up, the RAM content including the parity bit cannot be guaranteed. To avoid parity failures when reading RAM, the RAM has to be initialized. The RAM can be initialized by writing known values into it. When the known value is written, the corresponding parity bit will be automatically calculated and updated.

Another possibility to initialize the memory is to follow the Auto-Initialization of On-Chip SRAM Modules subsection in the *Architecture* chapter. The RAM will be initialized to 0. Depending on the even/odd parity selection, the parity bit will be calculated accordingly.

To allow for parity calculation during initialization, the parity functionality has to be enabled as discussed in [Section 16.2.15](#).

16.3 Control Registers and Control Packets

The DMA control registers are summarized in [Table 16-7](#). The base address for the control registers is FFFF F000h. The control packets are summarized in [Table 16-8](#). The base address for the control packets is FFF8 0000h. Each register begins on a word boundary. All registers and control packets are accessible in 8, 16, and 32 bit.

NOTE: The register definitions are given for a full DMA module configuration (32 channels, 64 requests, 2 Ports, Dual CPU support). Writes and Reads of bits pertaining to features not included in the DMA implementation as defined in the device-specific data manual are possible without error; however, they will have no affect on device operation.

Table 16-7. DMA Control Registers

16.3.1.2 Channel Pending Register (PEND)

Figure 16-19. Channel Pending Register (PEND) [offset = 04h]

LEGEND: R = Read only; -n = value after reset

Table 16-10. Channel Pending Register (PEND) Field Descriptions

| Bit | Field | Value | Description |
|-------|----------|-------|---|
| 31-16 | Reserved | 0 | Read returns 0. Writes have no effect. |
| 15-0 | PEND[n] | | Channel pending register. Bit 0 corresponds to channel 0, bit 1 corresponds to channel 1, and so on. Reading from PEND gives the channel pending information if the channel was initiated by SW or HW. Once set, it remains set even if the corresponding channel is disabled via HWCENA or SWCHENA. The pending bit is automatically cleared for the following conditions: <ul style="list-style-type: none"> At the end of a frame or a block transfer depending on how the channel is triggered as programmed in the TTYPE bit field of CHCTRL. The control packet is modified after the pending bit is set. An AHB bus error occurs. |
| | | 0 | The corresponding channel is inactive. |
| | | 1 | The corresponding channel is pending and is waiting for service. |

16.3.1.3 DMA Status Register (DMASTAT)

Figure 16-20. DMA Status Register (DMASTAT) [offset = 0Ch]

LEGEND: R = Read only; -n = value after reset

Table 16-11. DMA Status Register (DMASTAT) Field Descriptions

| Bit | Field | Value | Description |
|-------|----------|-------|--|
| 31-16 | Reserved | 0 | Read returns 0. Writes have no effect. |
| 15-0 | STCH[n] | | Status of DMA channels. Bit 0 corresponds to channel 0, bit 1 corresponds to channel 1, and so on. |
| | | 0 | The channel is inactive. |
| | | 1 | The channel is active; that is, the channel is currently in the DMA's execution queue. Note: The status of a channel currently in DMA's execution queue remains active even if emulation mode is entered or DMA is disabled via DMA_EN bit. |

16.3.1.4 HW Channel Enable Set and Status Register (HWCHENAS)

| Bit | Field | Value | Description |
|-------|------------|-------|--|
| 31-16 | Reserved | 0 | Read returns 0. Writes have no effect. |
| 15-0 | HWCHDIS[n] | | <p>HW channel disable bit. Bit 0 corresponds to channel 0, bit 1 corresponds to channel 1, and so on.</p> |
| | | 0 | <p>Read: The corresponding channel is disabled for HW triggering.</p> <p>Write: A write of zero to this bit has no effect.</p> |
| | | 1 | <p>Read: The corresponding channel is enabled for HW triggering.</p> <p>Write: The corresponding channel is disabled.</p> |

16.3.1.6 SW Channel Enable Set and Status Register (SWCHENAS)

Figure 16-23. SW Channel Enable Set and Status Register (SWCHENAS) [offset = 24h]

LEGEND: R/W = Read/Write; R = Read only; WP = Write in privilege mode only; -n = value after reset

Table 16-14. SW Channel Enable Set and Status Register (SWCHENAS) Field Descriptions

| Bit | Field | Value | Description |
|-------|------------|-------|---|
| 31-16 | Reserved | 0 | Read returns 0. Writes have no effect. |
| 15-0 | SWCHENA[n] | | <p>SW channel enable bit. Bit 0 corresponds to channel 0, bit 1 corresponds to channel 1, and so on. Writing a 1 to a bit triggers a SW request on the corresponding channel to start a DMA transaction. The corresponding bit is automatically cleared by the following conditions.</p> <ul style="list-style-type: none"> The corresponding bit is cleared after one frame transfer if the TTYPE bit in Channel Control Register (CHCTRL) is programmed for frame transfer. The corresponding bit is cleared after one block transfer if the corresponding TTYPE bit is programmed for block transfer and the auto-initiation bit is not enabled. The control packet is modified after the pending bit is set. The corresponding bit is cleared after one block transfer when TTYPE bit is programmed for blocks transfer and if the corresponding bit in HW channel enable register (HWCHENAS) is enabled. When a channel is enabled for both HW and SW, the state machine will initiate transfers based on the SW first. After one block transfer is complete, the corresponding bit in the SWCHENA register is then cleared. The same channel is serviced again by a HW DMA request. The corresponding bit is cleared if an AHB bus error is detected. <p>Reading from SWCHENAS gives the status (enabled/disabled) of channels 0 through 15.</p> |
| | | 0 | The corresponding channel is not triggered by SW request. |
| | | 1 | The corresponding channel is triggered by SW request. |

Table 16-42. BTC Interrupt Flag Register (BTCFLAG) Field Descriptions

| Bit | Field | Value | Description |
|-------|----------|-------|---|
| 31-16 | Reserved | 0 | Read returns 0. Writes have no effect. |
| 15-0 | BTCI[n] | 0 | Block transfer complete (BTC) flags. Bit 0 corresponds to channel 0, bit 1 corresponds to channel 1, and so on. Note: Reading from the respective interrupt channel offset register also clears the corresponding flag (see Section 16.3.1.39 and Section 16.3.1.43). Note: The state of the flag bit can be polled even if the corresponding interrupt enable bit is cleared. Read: A BTC interrupt of the corresponding channel is not pending. Write: Writing a zero to this bit has no effect. |
| | | 1 | Read: A BTC interrupt of the corresponding channel is pending. Write: The flag is cleared. |

16.3.1.35 BER Interrupt Flag Register (BERFLAG)

The BERFLAG will never be set in this device. The bus error reporting is handled by the DMA Read Imprecise Error and DMA Write Imprecise Error asserted to the ESM module directly, which are detected at the device level. See the ESM error mapping for the DMA Read/Write Imprecise Error.

16.3.1.36 FTCA Interrupt Channel Offset Register (FTCAOFFSET)

Figure 16-52. FTCA Interrupt Channel Offset Register (FTCAOFFSET) [offset = 14Ch]

LEGEND: R = Read only; -n = value after reset

Table 16-43. FTCA Interrupt Channel Offset Register (FTCAOFFSET) Field Descriptions

| Bit | Field | Value | Description |
|-------|----------|-------|--|
| 31-16 | Reserved | 0 | Read returns 0. Writes have no effect. |
| 7-6 | sbz | | These bits should always be programmed as zero. |
| 5-0 | FTCA | | Channel causing FTC interrupt Group A. These bits contain the channel number of the pending interrupt for Group A if the corresponding interrupt enable is set. Note: Reading this location clears the corresponding interrupt pending flag (see Section 16.3.1.31) with the highest priority. |
| | | 0 | No interrupt is pending. |
| | | 1h | Channel 0 is causing the pending interrupt Group A. |
| | | : | : |
| | | 10h | Channel 15 is causing the pending interrupt Group A. |

16.3.1.37 LFSA Interrupt Channel Offset Register (LFSAOFFSET)

Figure 16-53. LFSA Interrupt Channel Offset Register (LFSAOFFSET) [offset = 150h]

LEGEND: R = Read only; -n = value after reset

Table 16-44. LFSA Interrupt Channel Offset Register (LFSAOFFSET) Field Descriptions

| Bit | Field | Value | Description |
|-------|----------|-------|--|
| 31-16 | Reserved | 0 | Read returns 0. Writes have no effect. |
| 7-6 | sbz | | These bits should always be programmed as zero. |
| 5-0 | LFSA | | Channel causing LFS interrupt Group A. These bits contain the channel number of the pending interrupt for Group A if the corresponding interrupt enable is set. Note: Reading this location clears the corresponding interrupt pending flag (see Section 16.3.1.32) with the highest priority. |
| | | 0 | No interrupt is pending. |
| | | 1h | Channel 0 is causing the pending interrupt Group A. |
| | | : | : |
| | | 10h | Channel 15 is causing the pending interrupt Group A. |

16.3.1.38 HBCA Interrupt Channel Offset Register (HBCAOFFSET)

Figure 16-54. HBCA Interrupt Channel Offset Register (HBCAOFFSET) [offset = 154h]

LEGEND: R = Read only; -n = value after reset

Table 16-45. HBCA Interrupt Channel Offset Register (HBCAOFFSET) Field Descriptions

| Bit | Field | Value | Description |
|-------|----------|-------|--|
| 31-16 | Reserved | 0 | Read returns 0. Writes have no effect. |
| 7-6 | sbz | | These bits should always be programmed as zero. |
| 5-0 | HBCA | | Channel causing HBC interrupt Group A. These bits contain the channel number of the pending interrupt for Group A if the corresponding interrupt enable is set. Note: Reading this location clears the corresponding interrupt pending flag (see Section 16.3.1.33) with the highest priority. |
| | | 0 | No interrupt is pending. |
| | | 1h | Channel 0 is causing the pending interrupt Group A. |
| | | : | : |
| | | 10h | Channel 15 is causing the pending interrupt Group A. |

16.3.1.39 BTCA Interrupt Channel Offset Register (BTCAOFFSET)

Figure 16-55. BTCA Interrupt Channel Offset Register (BTCAOFFSET) [offset = 158h]

LEGEND: R = Read only; -n = value after reset

Table 16-46. BTCA Interrupt Channel Offset Register (BTCAOFFSET) Field Descriptions

| Bit | Field | Value | Description |
|-------|----------|-------|--|
| 31-16 | Reserved | 0 | Read returns 0. Writes have no effect. |
| 7-6 | sbz | | These bits should always be programmed as zero. |
| 5-0 | BTCA | | Channel causing BTC interrupt Group A. These bits contain the channel number of the pending interrupt for Group A if the corresponding interrupt enable is set. Note: Reading this location clears the corresponding interrupt pending flag (see Section 16.3.1.34) with the highest priority. |
| | | 0 | No interrupt is pending. |
| | | 1h | Channel 0 is causing the pending interrupt Group A. |
| | | : | : |
| | | 10h | Channel 15 is causing the pending interrupt Group A. |

16.3.1.40 FTCB Interrupt Channel Offset Register (FTCBOFFSET)

Figure 16-56. FTCB Interrupt Channel Offset Register (FTCBOFFSET) [offset = 160h]

LEGEND: R = Read only; -n = value after reset

Table 16-47. FTCB Interrupt Channel Offset Register (FTCBOFFSET) Field Descriptions

| Bit | Field | Value | Description |
|-------|----------|-------|--|
| 31-16 | Reserved | 0 | Read returns 0. Writes have no effect. |
| 7-6 | sbz | | These bits should always be programmed as zero. |
| 5-0 | FTCB | | Channel causing FTC interrupt Group B. These bits contain the channel number of the pending interrupt for Group B if the corresponding interrupt enable is set. Note: Reading this location clears the corresponding interrupt pending flag (see Section 16.3.1.31) with the highest priority. |
| | | 0 | No interrupt is pending. |
| | | 1h | Channel 0 is causing the pending interrupt Group B. |
| | | : | : |
| | | 10h | Channel 15 is causing the pending interrupt Group B. |

16.3.1.41 LFSB Interrupt Channel Offset Register (LFSBOFFSET)

Figure 16-57. LFSB Interrupt Channel Offset Register (LFSBOFFSET) [offset = 164h]

LEGEND: R = Read only; -n = value after reset

Table 16-48. LFSB Interrupt Channel Offset Register (LFSBOFFSET) Field Descriptions

| Bit | Field | Value | Description |
|-------|----------|-------|--|
| 31-16 | Reserved | 0 | Read returns 0. Writes have no effect. |
| 7-6 | sbz | | These bits should always be programmed as zero. |
| 5-0 | LFSB | | Channel causing LFS interrupt Group B. These bits contain the channel number of the pending interrupt for Group B if the corresponding interrupt enable is set. Note: Reading this location clears the corresponding interrupt pending flag (see Section 16.3.1.32) with the highest priority. |
| | | 0 | No interrupt is pending. |
| | | 1h | Channel 0 is causing the pending interrupt Group B. |
| | | : | : |
| | | 10h | Channel 15 is causing the pending interrupt Group B. |

16.3.1.42 HBCB Interrupt Channel Offset Register (HBCBOFFSET)

Figure 16-58. HBCB Interrupt Channel Offset Register (HBCBOFFSET) [offset = 168h]

LEGEND: R = Read only; -n = value after reset

Table 16-49. HBCB Interrupt Channel Offset Register (HBCBOFFSET) Field Descriptions

| Bit | Field | Value | Description |
|-------|----------|-------|---|
| 31-16 | Reserved | 0 | Read returns 0. Writes have no effect. |
| 7-6 | sbz | | These bits should always be programmed as zero. |
| 5-0 | HBCB | | Channel causing HBC interrupt Group B. These bits contain the channel number of the pending interrupt for Group B if the corresponding interrupt enable is set. Note: Reading this location clears the corresponding interrupt pending flag (see Section 16.3.1.33) with the highest priority. |
| | | 0 | No interrupt is pending. |
| | | 1h | Channel 0 is causing the pending interrupt Group B. |
| | | : | : |
| | | 10h | Channel 15 is causing the pending interrupt Group B. |

16.3.1.43 BTCB Interrupt Channel Offset Register (BTCBOFFSET)

Figure 16-59. BTCB Interrupt Channel Offset Register (BTCBOFFSET) [offset = 16Ch]

LEGEND: R = Read only; -n = value after reset

Table 16-50. BTCB Interrupt Channel Offset Register (BTCBOFFSET) Field Descriptions

| Bit | Field | Value | Description |
|-------|----------|-------|---|
| 31-16 | Reserved | 0 | Read returns 0. Writes have no effect. |
| 7-6 | sbz | | These bits should always be programmed as zero. |
| 5-0 | BTCB | | Channel causing BTC interrupt Group B. These bits contain the channel number of the pending interrupt for Group B if the corresponding interrupt enable is set. Note: Reading this location clears the corresponding interrupt pending flag (see Section 16.3.1.34) with the highest priority. |
| | | 0 | No interrupt is pending. |
| | | 1h | Channel 0 is causing the pending interrupt Group B. |
| | | : | : |
| | | 10h | Channel 15 is causing the pending interrupt Group B. |

16.3.1.44 Port Control Register (PTCRL)

Figure 16-60. Port Control Register (PTCRL) [offset = 178h]

| | | | | | | | | | | | | | | | | | |
|----|----------|--|--|--|--|--|--|--|--|--|----|--------|----------|----------|--|----|-------|
| 31 | Reserved | | | | | | | | | | | | | | | 25 | 24 |

| | R-0 | | | | | | | | | | | | | | | | |

LEGEND: R/W = Read/Write; R = Read only; WP = Write in privilege mode only; -n = value after reset

Table 16-51. Port Control Register (PTCRL) Field Descriptions

| Bit | Field | Value | Description |
|-------|----------|--------|---|
| 31-25 | Reserved | 0 | Read returns 0. Writes have no effect. |
| 24 | PENDB | 0 1 | Transfers pending for Port B. This flag determines if transfers are ongoing on port B. The flag will be cleared if no transfers are performed. It can be used to determine if there is still data transferred while DMA_EN is set to 0 in GCTCRL. In this case, once all transfers are finished, the flag will be set to 0. No transfers are pending. Transfers are pending. |
| 23-19 | Reserved | 0 | Read returns 0. Writes have no effect. |
| 18 | BYB | 0 1 | Bypass FIFO B. FIFO B is not bypassed. FIFO B is bypassed. Writing 1 to this bit limits the FIFO depth to the size of one element. That means that after one element is read, the write-out to the destination will begin. This feature is particularly useful to minimize switching latency between channels. Note: This feature does not make optimal use of bus bandwidth. |
| 17 | PSFRHQPB | 0 1 | Priority scheme fix or rotate for high priority queue of Port B. Fixed priority is used. Rotation priority is used. |
| 16 | PSFRLQPB | 0 1 | Priority scheme fix or rotate for low priority queue of Port B. The fixed priority scheme is used. The rotation priority scheme is used. |
| 15-0 | Reserved | 0 | Read returns 0. Writes have no effect. |

16.3.1.45 RAM Test Control (RTCTRL)

Figure 16-61. RAM Test Control (RTCTRL) [offset = 17Ch]

LEGEND: R/W = Read/Write; R = Read only; WP = Write in privilege mode only; -n = value after reset

Table 16-52. RAM Test Control (RTCTRL) Field Descriptions

| Bit | Field | Value | Description |
|------|----------|-------|--|
| 31-1 | Reserved | 0 | Read returns 0. Writes have no effect. |
| 0 | RTC | | RAM Test Control. Writing a one to this bit opens the write access to the reserved locations of control packet RAM as defined in the memory map. Note: This bit should be set to zero during normal operation. |
| | | 0 | RAM Test Control Disabled. |
| | | 1 | RAM Test Control Enabled.. |

16.3.1.46 Debug Control (DCTRL)

Figure 16-62. Debug Control (DCTRL) [offset = 180h]

| | | | | | | |
|----------|----|----------|----|----------|----|---------|
| 31 | 29 | 28 | 24 | 23 | 17 | 16 |
| Reserved | | CHNUM | | Reserved | | DMADBGS |
| R-0 | | R-0 | | R-0 | | R/WC-0 |
| 15 | | | | | 1 | 0 |
| | | Reserved | | | | DBGEN |
| | | R-0 | | | | R/WC-0 |

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 16-53. Debug Control (DCTRL) Field Descriptions

| Bit | Field | Value | Description |
|-------|----------|-------|---|
| 31-29 | Reserved | 0 | Read returns 0. Writes have no effect. |
| 28-24 | CHNUM | 0-1Fh | Channel Number. This bit field indicates the channel number that causes the watchpoint to match. |
| 23-17 | Reserved | 0 | Read returns 0. Writes have no effect. |
| 16 | DMADBGS | 0 | DMA debug status. When a watchpoint is set up to watch for a unique bus address or a range of addresses is true on one of the three bus ports, then the DMA debug status bit is set to 1 and a debug request signal is asserted to the main CPU. The CPU must write a 1 to clear this bit for the DMA controller to release the debug request signal. Read: No watchpoint condition is detected. Write: Writing a zero to this bit has no effect. |
| | | 1 | Read: The watchpoint condition is detected. Write: The bit is cleared. |
| 15-1 | Reserved | 0 | Read returns 0. Writes have no effect. |
| 0 | DBGEN | 0 | Debug Enable. Note: This bit can only be set when using a debugger. Note: This bit is reset when Test reset (nTRST) is low. Debug is disabled. |
| | | 1 | The watchpoint checking logics is enabled. |

16.3.1.47 Watch Point Register (WPR)

Figure 16-63. Watch Point Register (WPR) [offset = 184h]

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 16-54. Watch Point Register (WPR) Field Descriptions

| Bit | Field | Value | Description |
|------|-------|--------------|--|
| 31-0 | WP | 0-FFFF FFFFh | Watch point. Note: These bits can only be set when using a debugger. This register is only reset by a test reset (nTRST). A 32-bit address can be programmed into this register as a watchpoint. This register is used with the watch mask register (WMR). When the DBGEN bit in the DCTRL register is set and a unique address or a range of addresses are detected on the AHB address bus of Port B, a debug request signal is sent to the ARM CPU. The state machine of the port in which the watchpoint condition is true is frozen. |

16.3.1.48 Watch Mask Register (WMR)

Figure 16-64. Watch Mask Register (WMR) [offset = 188h]

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 16-55. Watch Mask Register (WMR) Field Descriptions

| Bit | Field | Value | Description |
|------|-------|--------|---|
| 31-0 | WM[n] | 0 1 | Watch mask. Note: These bits can only be set when using a debugger. This register is only reset by a test reset (nTRST). Setting a bit to 0 allows the bit in the WPR register to be used for address matching for a watch point. Setting a bit to 1 in the WMR register masks the corresponding bit in the WPR register and is disregarded in the comparison. |

16.3.1.49 Port B Active Channel Source Address Register (PBACSADDR)

Figure 16-65. Port B Active Channel Source Address Register (PBACDADDR) [offset = 198h]

LEGEND: R = Read only; -n = value after reset

Table 16-56. Port B Active Channel Source Address Register (PBACDADDR) Field Descriptions

| Bit | Field | Value | Description |
|------|--------|--------------|--|
| 31-0 | PBACSA | 0-FFFF FFFFh | Port B Active Channel Source Address. This register contains the current source address of the active channel as broadcasted in Section 16.3.1.3 for Port B. |

16.3.1.50 Port B Active Channel Destination Address Register (PBACDADDR)

Figure 16-66. Port B Active Channel Destination Address Register (PBACDADDR) [offset = 19Ch]

LEGEND: R = Read only; -n = value after reset

Table 16-57. Port B Active Channel Destination Address Register (PBACDADDR) Field Descriptions

| Bit | Field | Value | Description |
|------|--------|--------------|--|
| 31-0 | PBACDA | 0-FFFF FFFFh | Port B Active Channel Destination Address. This register contains the current destination address of the active channel as broadcasted in Section 16.3.1.3 for Port B. |

16.3.1.52 Parity Control Register (DMAPCR)

Figure 16-68. Parity Control Register (DMAPCR) [offset = 1A8h]

| | | | | | | | | | | | | | |
|----------|---|--|--|--------|----------|-----|--|--|------------|---------|--|--------|----|
| 31 | | | | | | | | | | | | 15 | 16 |

| R-0 | | | | | | | | | | | | R/WP-0 | |
| 15 | 9 | | | 8 | 7 | 4 | | | 3 | 0 | | | |
| Reserved | | | | TEST | Reserved | | | | PARITY_ENA | | | | |
| R-0 | | | | R/WP-0 | | R-0 | | | | R/WP-5h | | | |

LEGEND: R/W = Read/Write; R = Read only; WP = Write in privilege mode only; -n = value after reset

Table 16-59. Parity Control Register (DMAPCR) Field Descriptions

| Bit | Field | Value | Description |
|-------|------------|------------------|--|
| 31-17 | Reserved | 0 | Read returns 0. Writes have no effect. |
| 16 | ERRA | 0 | Error action. |
| | | 1 | If a parity error is detected on control packet x (x = 0, 1, ... n), then the enable/disable state of control packet x remains unchanged. |
| | | | If a parity error is detected on control packet x (x = 0, 1, ...n), then the DMA controller is disabled immediately. If a frame on control packet x is processed at the time the parity error is detected, then remaining elements of this frame will not be transferred anymore. The DMA will be disabled regardless of whether the error was detected during a read to the control packet RAM performed by the DMA state machine or by a different master. |
| 15-9 | Reserved | 0 | Read returns 0. Writes have no effect. |
| 8 | TEST | 0 | When this bit is set, the parity bits are memory mapped to make them accessible by the CPU. |
| | | 1 | The parity bits are not memory mapped. |
| | | | The parity bits are memory mapped. |
| 7-4 | Reserved | 0 | Read returns 0. Writes have no effect. |
| 3-0 | PARITY_ENA | 5h | Parity error detection enable. This bit field enables or disables the parity check on read operations and the parity calculation on write operations. If parity checking is enabled and a parity error is detected the DMA_UERR signal is activated. |
| | | All other values | The parity check is disabled. |
| | | | The parity check is enabled. |
| | | | Note: It is recommended to write Ah to enable parity check, to guard against soft error from flipping PARITY_ENA to a disable state. |

16.3.1.53 DMA Parity Error Address Register (DMAPAR)

Figure 16-69. DMA Parity Error Address Register (DMAPAR) [offset = 1ACh]

LEGEND: R/W = Read/Write; R = Read only; W1C = Write 1 to clear; X= Undefined; -n = value after reset

Table 16-60. DMA Parity Error Address Register (DMAPAR) Field Descriptions

| Bit | Field | Value | Description |
|-------|--------------|--------|--|
| 31-25 | Reserved | 0 | Read returns 0. Writes have no effect. |
| 24 | EDFLAG | 0 | Parity Error Detection Flag. This flag indicates if a parity error occurred on reading DMA Control packet RAM. Read: No error occurred. Write: No effect. |
| | | 1 | Read: Error detected and the address is captured in DMAPAR's ERROR_ADDRESS field Write: Clears the bit. |
| 23-12 | Reserved | 0 | Read returns 0. Writes have no effect. |
| 11-0 | ERRORADDRESS | 0-FFFh | Error address. These bits hold the address of the first parity error generated in the RAM. This error address is frozen from being updated until it is read by the CPU. During emulation mode when SUSPEND is high, this address is frozen even when read. Note: The error address register will not be reset by PORRST nor by any other reset source. |

16.3.1.54 DMA Memory Protection Control Register (DMAMPCTRL)

All other transfers are rounded up to the nearest 32-bit word end address.</p> |

16.3.2 Channel Configuration

The channel configuration is defined by the channel control packet: channel control, transfer count, index pointers, source/destination address.

- It is stored in local RAM, which is protected by parity.
- Each control packet contains a total of nine fields.
- The first six fields are programmable, while the last three fields are read only.
- The RAM is accessible by queue A and queue B state machines as well as CPU.
- When there are simultaneous accesses, the priority is resolved in a fixed priority scheme with the CPU having the highest priority.

All the control packets look the same. Following, there is the detailed layout of these registers shown for control packet 0.

16.3.2.1 Initial Source Address (ISADDR)

Figure 16-80. Initial Source Address (ISADDR) [offset = 00]

LEGEND: R/W = Read/Write; R = Read only; WP = Write in privilege mode only; -n = value after reset; X = Unknown

Table 16-71. Initial Source Address (ISADDR) Field Descriptions

| Bit | Field | Value | Description |
|------|--------|--------------|--|
| 31-0 | ISADDR | 0-FFFF FFFFh | Initial source address. These bits give the absolute 32-bit source address (physical). |

16.3.2.2 Initial Destination Address Register (IDADDR)

Figure 16-81. Initial Destination Address Register (IDADDR) [offset = 04h]

LEGEND: R/W = Read/Write; R = Read only; WP = Write in privilege mode only; -n = value after reset; X = Unknown

Table 16-72. Initial Destination Address Register (IDADDR) Field Descriptions

| Bit | Field | Value | Description |
|------|--------|--------------|--|
| 31-0 | IDADDR | 0-FFFF FFFFh | Initial destination address. These bits give the absolute 32-bit destination address (physical). |

16.3.2.3 Initial Transfer Count Register (ITCOUNT)

Table 16-79. Current Transfer Count Register (CTCOUNT) Field Descriptions

| Bit | Field | Value | Description |
|-------|----------|---------|---|
| 31-29 | Reserved | 0 | Reads are undefined. Writes have no effect. |
| 28-16 | CFTCOUNT | 0-1FFFh | Current frame transfer count. Returned the current remaining frame counts. |
| 15-13 | Reserved | 0 | Reads are undefined. Writes have no effect. |
| 12-0 | CETCOUNT | 0-1FFFh | Current element transfer count. These bits return the current remaining element counts. CTCOUNT register is only updated after a channel is arbitrated out of the priority queue. |

External Memory Interface (EMIF)

This chapter describes the external memory Interface (EMIF).

| Topic | Page |
|--|-------------|
| 17.1 Introduction | 633 |
| 17.2 EMIF Module Architecture | 635 |
| 17.3 EMIF Registers | 667 |
| 17.4 Example Configuration..... | 679 |

17.1 Introduction

17.1.1 Purpose of the Peripheral

This EMIF memory controller is compliant with the JESD21-C SDR SDRAM memories utilizing a 16-bit data bus. The purpose of this EMIF is to provide a means for the CPU to connect to a variety of external devices including:

- Single data rate (SDR) SDRAM
- Asynchronous devices including NOR Flash and SRAM

The most common use for the EMIF is to interface with both a flash device and an SDRAM device simultaneously. contains an example of operating the EMIF in this configuration.

17.1.2 Features

The EMIF includes many features to enhance the ease and flexibility of connecting to external SDR SDRAM and asynchronous devices.

17.1.2.1 Asynchronous Memory Support

EMIF supports asynchronous:

- SRAM memories
- NOR Flash memories

The EMIF data bus width is up to 16 bits and there are up to 13 address lines. There is an external wait input that allows slower asynchronous memories to extend the memory access. The EMIF module supports up to 3 chip selects (EMIF_nCS[4:2]). Each chip select has the following individually programmable attributes:

- Data Bus Width
- Read cycle timings: setup, hold, strobe
- Write cycle timings: setup, hold, strobe
- Bus turn-around time
- Extended Wait Option with Programmable Timeout
- Select Strobe option

17.1.2.2 Synchronous DRAM Memory Support

The EMIF module supports 16-bit SDRAM in addition to the asynchronous memories listed in [Section 17.1.2.1](#). It has a single SDRAM chip select (EMIF_nCS[0]). SDRAM configurations that are supported are:

- One, Two, and Four Bank SDRAM devices
- Devices with Eight, Nine, Ten, and Eleven Column Address
- CAS Latency of two or three clock cycles
- 16-bit Data Bus Width
- 3.3V LVCMOS Interface

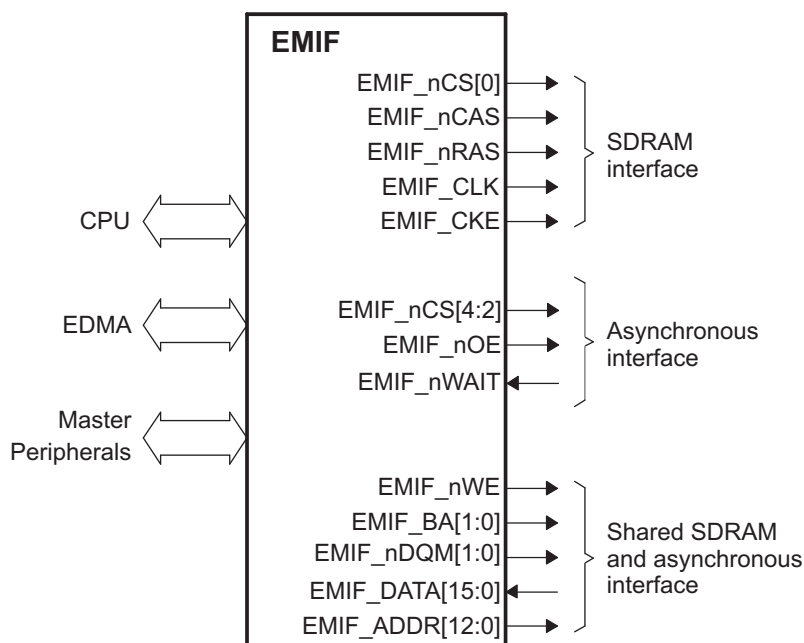

Additionally, the EMIF supports placing the SDRAM in Self-Refresh and Powerdown modes. Self-refresh mode allows the SDRAM to be put in a low-power state while still retaining memory contents; since the SDRAM will continue to refresh itself even without clocks from the microcontroller. Powerdown mode achieves even lower power, except the microcontroller must periodically wake up and issue refreshes if data retention is required.

Note that the EMIF module does not support Mobile SDRAM devices.

17.1.3 Functional Block Diagram

Figure 17-1 illustrates the connections between the EMIF and its internal requesters, along with the external EMIF pins. Section 17.2.2 contains a description of the entities internal to the SoC that can send requests to the EMIF, along with their prioritization. Section 17.2.3 describes the EMIF external pins and summarizes their purpose when interfacing with SDRAM and asynchronous devices.

Figure 17-1. EMIF Functional Block Diagram

17.2 EMIF Module Architecture

This section provides details about the architecture and operation of the EMIF. Both, SDRAM and asynchronous Interface are covered, along with other system-related issues such as clock control.

17.2.1 EMIF Clock Control

The EMIF clock is output on the EMIF_CLK pin and should be used when interfacing to external SDRAM devices. The EMIF module gets the VCLK3 clock domain as the input. This clock domain is running at half the frequency of the main oscillator by default, that is, between 2.5MHz to 10MHz. The VCLK3 frequency is divided down from the HCLK domain frequency by a programmable divider (/1 to /16). Refer the Architecture chapter of the device technical reference manual for more information on configuring the VCLK3 domain frequency.

17.2.2 EMIF Requests

Different sources within the SoC can make requests to the EMIF. These requests consist of accesses to SDRAM memory, asynchronous memory, and EMIF registers. The EMIF can process only one request at a time. Therefore a high performance crossbar switch exists within the SoC to provide prioritized requests from the different sources to the EMIF. The sources are:

1. CPU
2. DMA
3. Other master peripherals

If a request is submitted from two or more sources simultaneously, the crossbar switch will forward the highest priority request to the EMIF first. Upon completion of a request, the crossbar switch again evaluates the pending requests and forwards the highest priority pending request to the EMIF.

When the EMIF receives a request, it may or may not be immediately processed. In some cases, the EMIF will perform one or more auto refresh cycles before processing the request. For details on the EMIF's internal arbitration between performing requests and performing auto refresh cycles, see [Section 17.2.13](#).

17.2.3 EMIF Signal Descriptions

This section describes the function of each of the EMIF signals.

Table 17-1. EMIF Pins Used to Access Both SDRAM and Asynchronous Memories

| Pins(s) | I/O | Description |
|-----------------|-----|---|
| EMIF_DATA[15:0] | I/O | EMIF data bus. |
| EMIF_ADDR[12:0] | O | EMIF address bus. When interfacing to an SDRAM device, these pins are primarily used to provide the row and column address to the SDRAM. The mapping from the internal program address to the external values placed on these pins can be found in Table 17-13 . EMIF_A[10] is also used during the PRE command to select which banks to deactivate. When interfacing to an asynchronous device, these pins are used in conjunction with the EMIF_BA pins to form the address that is sent to the device. The mapping from the internal program address to the external values placed on these pins can be found in Section 17.2.6.1 . |
| EMIF_BA[1:0] | O | EMIF bank address. When interfacing to an SDRAM device, these pins are used to provide the bank address inputs to the SDRAM. The mapping from the internal program address to the external values placed on these pins can be found in Table 17-13 . When interfacing to an asynchronous device, these pins are used in conjunction with the EMIF_A pins to form the address that is sent to the device. The mapping from the internal program address to the external values placed on these pins can be found in Section 17.2.6.1 . |
| EMIF_nDQM[1:0] | O | Active-low byte enables. When interfacing to SDRAM, these pins are connected to the DQM pins of the SDRAM to individually enable/disable each of the bytes in a data access. When interfacing to an asynchronous device, these pins are connected to byte enables. See Section 17.2.6 for details. |

Table 17-1. EMIF Pins Used to Access Both SDRAM and Asynchronous Memories (continued)

| Pin(s) | I/O | Description |
|----------|-----|---|
| EMIF_nWE | O | Active-low write enable. When interfacing to SDRAM, this pin is connected to the nWE pin of the SDRAM and is used to send commands to the device. When interfacing to an asynchronous device, this pin provides a signal which is active-low during the strobe period of an asynchronous write access cycle. |

Table 17-2. EMIF Pins Specific to SDRAM

| Pin(s) | I/O | Description |
|-------------|-----|--|
| EMIF_nCS[0] | O | Active-low chip enable pin for SDRAM devices. This pin is connected to the chip-select pin of the attached SDRAM device and is used for enabling/disabling commands. By default, the EMIF keeps this SDRAM chip select active, even if the EMIF is not interfaced with an SDRAM device. This pin is deactivated when accessing the asynchronous memory bank and is reactivated on completion of the asynchronous access. |
| EMIF_nRAS | O | Active-low row address strobe pin. This pin is connected to the nRAS pin of the attached SDRAM device and is used for sending commands to the device. |
| EMIF_nCAS | O | Active-low column address strobe pin. This pin is connected to the nCAS pin of the attached SDRAM device and is used for sending commands to the device. |
| EMIF_CKE | O | Clock enable pin. This pin is connected to the CKE pin of the attached SDRAM device and is used for issuing the SELF REFRESH command which places the device in self refresh mode. See Section 17.2.5.7 for details. |
| EMIF_CLK | O | SDRAM clock pin. This pin is connected to the CLK pin of the attached SDRAM device. See Section 17.2.1 for details on the clock signal. |

Table 17-3. EMIF Pins Specific to Asynchronous Memory

| Pin(s) | I/O | Description |
|---------------|-----|--|
| EMIF_nCS[4:2] | O | Active-low chip enable pins for asynchronous devices. These pins are meant to be connected to the chip-select pins of the attached asynchronous device. These pins are active only during accesses to the asynchronous memory. |
| EMIF_nWAIT | I | Wait input with programmable polarity. A connected asynchronous device can extend the strobe period of an access cycle by asserting the EMIF_nWAIT input to the EMIF as described in Section 17.2.6.6 . To enable this functionality, the EW bit in the asynchronous 1 configuration register (CE2CFG) must be set to 1. In addition, the WP0 bit in CE2CFG must be configured to define the polarity of the EMIF_nWAIT pin. |
| EMIF_nOE | O | Active-low pin enable for asynchronous devices. This pin provides a signal which is active-low during the strobe period of an asynchronous read access cycle. |

17.2.4 EMIF Signal Multiplexing Control

Several EMIF signals are multiplexed with other functions on this microcontroller. Please refer to the I/O Multiplexing Module chapter of the technical reference manual for more information on how to enable the output of these EMIF signals.

17.2.5 SDRAM Controller and Interface

The EMIF can gluelessly interface to most standard SDR SDRAM devices and supports such features as self refresh mode and prioritized refresh. In addition, it provides flexibility through programmable parameters such as the refresh rate, CAS latency, and many SDRAM timing parameters. The following sections include details on how to interface and properly configure the EMIF to perform read and write operations to externally connected SDR SDRAM devices. Also, provides a detailed example of interfacing the EMIF to a common SDRAM device.

17.2.5.1 SDRAM Commands

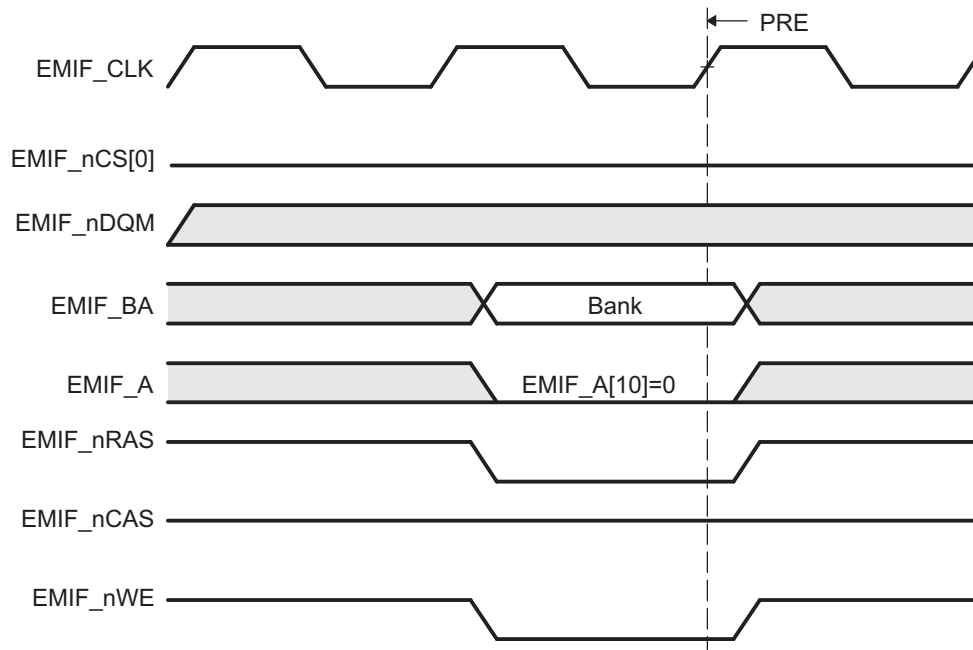

The EMIF supports the SDRAM commands described in [Table 17-4](#). [Table 17-5](#) shows the truth table for the SDRAM commands, and an example timing waveform of the PRE command is shown in [Figure 17-2](#). EMIF_A[10] is pulled low in this example to deactivate only the bank specified by the EMIF_BA pins.

Table 17-4. EMIF SDRAM Commands

| Command | Function |
|---------|--|
| PRE | Precharge. Depending on the value of EMIF_A[10], the PRE command either deactivates the open row in all banks (EMIF_A[10] = 1) or only the bank specified by the EMIF_BA[1:0] pins (EMIF_A[10] = 0). |
| ACTV | Activate. The ACTV command activates the selected row in a particular bank for the current access. |
| READ | Read. The READ command outputs the starting column address and signals the SDRAM to begin the burst read operation. Address EMIF_A[10] is always pulled low to avoid auto precharge. This allows for better bank interleaving performance. |
| WRT | Write. The WRT command outputs the starting column address and signals the SDRAM to begin the burst write operation. Address EMIF_A[10] is always pulled low to avoid auto precharge. This allows for better bank interleaving performance. |
| BT | Burst terminate. The BT command is used to truncate the current read or write burst request. |
| LMR | Load mode register. The LMR command sets the mode register of the attached SDRAM devices and is only issued during the SDRAM initialization sequence described in Section 17.2.5.4 . |
| REFR | Auto refresh. The REFR command signals the SDRAM to perform an auto refresh according to its internal address. |
| SLFR | Self refresh. The self refresh command places the SDRAM into self refresh mode, during which it provides its own clock signal and auto refresh cycles. |
| NOP | No operation. The NOP command is issued during all cycles in which one of the above commands is not issued. |

Table 17-5. Truth Table for SDRAM Commands

| SDRAM Pins: | CKE | nCS | nRAS | nCAS | nWE | BA[1:0] | A[12:11] | A[10] | A[9:0] |
|-------------|----------|-------------|-----------|-----------|----------|--------------|---------------|------------|-------------|

Figure 17-2. Timing Waveform of SDRAM PRE Command

17.2.5.2 Interfacing to SDRAM

The EMIF supports a glueless interface to SDRAM devices with the following characteristics:

- Pre-charge bit is A[10]
- The number of column address bits is 8, 9, 10, or 11.
- The number of row address bits is 13, 14, 15, or 16.
- The number of internal banks is 1, 2, or 4.

Figure 17-3 shows an interface between the EMIF and a 2M x 16 x 4 bank SDRAM device, and Figure 17-4 shows an interface between the EMIF and a 512K x 16 x 2 bank SDRAM device. For devices supporting 16-bit interface, refer to Table 17-6 for list of commonly-supported SDRAM devices and the required connections for the address pins.

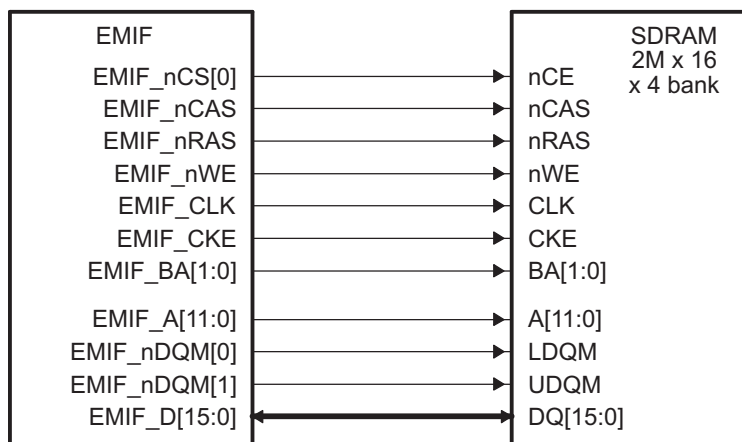

Figure 17-3. EMIF to 2M x 16 x 4 bank SDRAM Interface

Figure 17-4. EMIF to 512K x 16 x 2 bank SDRAM Interface

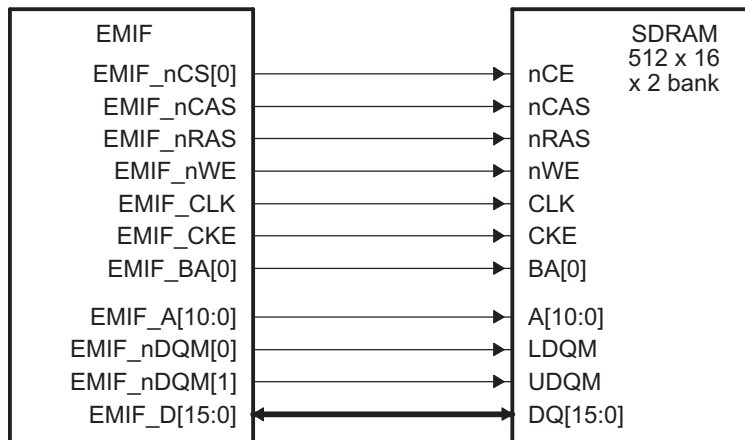

Table 17-6. 16-bit EMIF Address Pin Connections

| SDRAM Size | Width | Banks | Device | Address Pins |
|------------|-------|-------|--------|--------------|
| 16M bits | x16 | 2 | SDRAM | A[10:0] |
| | | | EMIF | EMIF_A[10:0] |
| 64M bits | x16 | 4 | SDRAM | A[11:0] |
| | | | EMIF | EMIF_A[11:0] |

| | | | EMIF | EMIF_A[12:0] |
| 512M bits | x16 | 4 | SDRAM | A[12:0] |
| | | | EMIF | EMIF_A[12:0] |

17.2.5.3 SDRAM Configuration Registers

The operation of the EMIF's SDRAM interface is controlled by programming the appropriate configuration registers. This section describes the purpose and function of each configuration register, but [Section 17.3](#) should be referred for a more detailed description of each register, including the default registers values and bit-field positions. The following tables list the four such configuration registers, along with a description of each of their programmable fields.

NOTE: Writing to any of the fields: NM, CL, IBANK, and PAGESIZE in the SDRAM configuration register (SDCR) causes the EMIF to abandon whatever it is currently doing and trigger the SDRAM initialization procedure described in [Section 17.2.5.4](#).

Table 17-7. Description of the SDRAM Configuration Register (SDCR)

| Parameter | Description |
|-----------|---|
| SR | This bit controls entering and exiting of the Self-Refresh mode. The field should be written using a byte-write to the upper byte of SDCR to avoid triggering the SDRAM initialization sequence. |
| PD | This bit controls entering and exiting of the Power down mode. The field should be written using a byte-write to the upper byte of SDCR to avoid triggering the SDRAM initialization sequence. If both SR and PD bits are set, the EMIF will go into Self Refresh. |
| PDWR | Perform refreshes during Power Down. Writing a 1 to this bit will cause the EMIF to exit the power down state and issue an AUTO REFRESH command every time Refresh May level is set. The field should be written using a byte-write to the upper byte of SDCR to avoid triggering the SDRAM initialization sequence. This bit should be set along with PD when entering power-down mode. |
| NM | Narrow Mode. This bit defines the width of the data bus between the EMIF and the attached SDRAM device. When set to 1, the data bus is set to 16-bits. When set to 0, the data bus is set to 32-bits. This bit must always be set to 1. |
| CL | CAS latency. This field defines the number of clock cycles between when an SDRAM issues a READ command and when the first piece of data appears on the bus. The value in this field is sent to the attached SDRAM device via the LOAD MODE REGISTER command during the SDRAM initialization procedure as described in Section 17.2.5.4 . Only, values of 2h (CAS latency = 2) and 3h (CAS latency = 3) are supported and should be written to this field. A 1 must be simultaneously written to the BIT11_9LOCK bit field of SDCR in order to write to the CL bit field. |
| IBANK | Number of Internal SDRAM Banks. This field defines the number of banks inside the attached SDRAM devices in the following way: <ul style="list-style-type: none"> When IBANK = 0, 1 internal bank is used When IBANK = 1h, 2 internal banks are used When IBANK = 2h, 4 internal banks are used This field value affects the mapping of logical addresses to SDRAM row, column, and bank addresses. See Section 17.2.5.11 for details. |
| PAGESIZE | Page Size. This field defines the internal page size of the attached SDRAM devices in the following way: <ul style="list-style-type: none"> When PAGESIZE = 0, 256-word pages are used When PAGESIZE = 1h, 512-word pages are used When PAGESIZE = 2h, 1024-word pages are used When PAGESIZE = 3h, 2048-word pages are used This field value affects the mapping of logical addresses to SDRAM row, column, and bank addresses. See Section 17.2.5.11 for details. |

Table 17-8. Description of the SDRAM Refresh Control Register (SDRCR)

| Parameter | Description |
|-----------|---|
| RR | Refresh Rate. This field controls the rate at which attached SDRAM devices will be refreshed. The following equation can be used to determine the required value of RR for an SDRAM device: <ul style="list-style-type: none"> $RR = f_{EMIF_CLK} / (\text{Required SDRAM Refresh Rate})$ More information about the operation of the SDRAM refresh controller can be found in Section 17.2.5.6 . |

Table 17-9. Description of the SDRAM Timing Register (SDTIMR)

| Parameter | Description |
|-----------|---|
| T_RFC | SDRAM Timing Parameters. These fields configure the EMIF to comply with the AC timing requirements of the attached SDRAM devices. This allows the EMIF to avoid violating SDRAM timing constraints and to more efficiently schedule its operations. More details about each of these parameters can be found in the register description in Section 17.3.6 . These parameters should be set to satisfy the corresponding timing requirements found in the SDRAM's datasheet. |

| T_RRD | |

Table 17-10. Description of the SDRAM Self Refresh Exit Timing Register (SDSRETR)

| Parameter | Description |
|-----------|--|
| T_XS | Self Refresh Exit Parameter. The T_XS field of this register informs the EMIF about the minimum number of EMIF_CLK cycles required between exiting Self Refresh and issuing any command. This parameter should be set to satisfy the t_{XSR} value for the attached SDRAM device. |

17.2.5.4 SDRAM Auto-Initialization Sequence

The EMIF automatically performs an SDRAM initialization sequence, regardless of whether it is interfaced to an SDRAM device, when either of the following two events occur:

- The EMIF comes out of reset. No memory accesses to the SDRAM and Asynchronous interfaces are performed until this auto-initialization is complete.
- A write is performed to any of the three least significant bytes of the SDRAM configuration register (SDCR)

An SDRAM initialization sequence consists of the following steps:

1. If the initialization sequence is activated by a write to SDCR, and if any of the SDRAM banks are open, the EMIF issues a PRE command with EMIF_A[10] held high to indicate all banks. This is done so that the maximum ACTV to PRE timing for an SDRAM is not violated.
2. The EMIF drives EMIF_CKE high and begins continuously issuing NOP commands until eight SDRAM refresh intervals have elapsed. An SDRAM refresh interval is equal to the value of the RR field of SDRAM refresh control register (SDRCR), divided by the frequency of EMIF_CLK (RR/f_{EMIF_CLK}). This step is used to avoid violating the Power-up constraint of most SDRAM devices that requires 200 μ s (sometimes 100 μ s) between receiving stable Vdd and CLK and the issuing of a PRE command. Depending on the frequency of EMIF_CLK, this step may or may not be sufficient to avoid violating the SDRAM constraint. See [Section 17.2.5.5](#) for more information.
3. After the refresh intervals have elapsed, the EMIF issues a PRE command with EMIF_A[10] held high to indicate all banks.
4. The EMIF issues eight AUTO REFRESH commands.
5. The EMIF issues the LMR command with the EMIF_A[9:0] pins set as described in [Table 17-11](#).
6. Finally, the EMIF performs a refresh cycle, which consists of the following steps:
 - (a) Issuing a PRE command with EMIF_A[10] held high if any banks are open
 - (b) Issuing an REF command

Table 17-11. SDRAM LOAD MODE REGISTER Command

| EMIF_A[9:7] | EMIF_A[6:4] | EMIF_A[3] | EMIF_A[2:0] |
|--|---|---|--|
| 0 (Write bursts are of the programmed burst length in EMIF_A[2:0]) | These bits control the CAS latency of the SDRAM and are set according to CL field in the SDRAM configuration register (SDCR) as follows: <ul style="list-style-type: none"> If CL = 2, EMIF_A[6:4] = 2h (CAS latency = 2) If CL = 3, EMIF_A[6:4] = 3h (CAS latency = 3) | 0 (Sequential Burst Type. Interleaved Burst Type not supported) | These bits control the burst length of the SDRAM and are set according to the NM field in the SDRAM configuration register (SDCR) as follows: <ul style="list-style-type: none"> If NM = 0, EMIF_A[2:0] = 2h (Burst Length = 4) If NM = 1, EMIF_A[2:0] = 3h (Burst Length = 8) |

17.2.5.5 SDRAM Configuration Procedure

There are two different SDRAM configuration procedures. Although EMIF automatically performs the SDRAM initialization sequence described in [Section 17.2.5.4](#) when coming out of reset, it is recommended to follow one of the procedures listed below before performing any EMIF memory requests. Procedure A should be followed if it is determined that the SDRAM Power-up constraint was not violated during the SDRAM Auto-Initialization Sequence detailed in [Section 17.2.5.4](#) on coming out of Reset. The SDRAM Power-up constraint specifies that 200 μ s (sometimes 100 μ s) should exist between receiving stable Vdd and CLK and the issuing of a PRE command. Procedure B should be followed if the SDRAM Power-up constraint was violated. The 200 μ s (100 μ s) SDRAM Power-up constraint will be violated if the frequency of EMIF_CLK is greater than 50 MHz (100 MHz for 100 μ s SDRAM power-up constraint) during SDRAM Auto-Initialization Sequence. Procedure B should be followed if there is any doubt that the Power-up constraint was not met.

Procedure A — Following is the procedure to be followed if the SDRAM Power-up constraint was NOT violated:

1. Place the SDRAM into Self-Refresh Mode by setting the SR bit of SDCR to 1. A byte-write to the upper byte of SDCR should be used to avoid restarting the SDRAM Auto-Initialization Sequence described in [Section 17.2.5.4](#). The SDRAM should be placed into Self-Refresh mode when changing the frequency of EMIF_CLK to avoid incurring the 200 μ s Power-up constraint again.
2. Configure the desired EMIF_CLK clock frequency. The frequency of the memory clock must meet the timing requirements in the SDRAM manufacturer's documentation and the timing limitations shown in the electrical specifications of the device datasheet.
3. Remove the SDRAM from Self-Refresh Mode by clearing the SR bit of SDCR to 0. A byte-write to the upper byte of SDCR should be used to avoid restarting the SDRAM Auto-Initialization Sequence described in [Section 17.2.5.4](#).
4. Program SDTIMR and SDSRETR to satisfy the timing requirements for the attached SDRAM device. The timing parameters should be taken from the SDRAM datasheet.
5. Program the RR field of SDCRCR to match that of the attached device's refresh interval. See [Section 17.2.5.6.1](#) details on determining the appropriate value.
6. Program SDCR to match the characteristics of the attached SDRAM device. This will cause the auto-initialization sequence in [Section 17.2.5.4](#) to be re-run. This second initialization generally takes much less time due to the increased frequency of EMIF_CLK.

Procedure B — Following is the procedure to be followed if the SDRAM Power-up constraint was violated:

1. Configure the desired EMIF_CLK clock frequency. The frequency of the memory clock must meet the timing requirements in the SDRAM manufacturer's documentation and the timing limitations shown in the electrical specifications of the device datasheet.
2. Program SDTIMR and SDSRETR to satisfy the timing requirements for the attached SDRAM device. The timing parameters should be taken from the SDRAM datasheet.
3. Program the RR field of SDCRCR such that the following equation is satisfied: $(RR \times 8) / (f_{EMIF_CLK}) > 200 \mu s$ (sometimes 100 μ s). For example, an EMIF_CLK frequency of 100 MHz would require setting RR to 2501 (9C5h) or higher to meet a 200 μ s constraint.

4. Program SDCR to match the characteristics of the attached SDRAM device. This will cause the auto-initialization sequence in [Section 17.2.5.4](#) to be re-run with the new value of RR.
5. Perform a read from the SDRAM to assure that step 5 of this procedure will occur after the initialization process has completed. Alternatively, wait for 200 μ s instead of performing a read.
6. Finally, program the RR field to match that of the attached device's refresh interval. See [Section 17.2.5.6.1](#) details on determining the appropriate value.

After following the above procedure, the EMIF is ready to perform accesses to the attached SDRAM device. See for an example of configuring the SDRAM interface.

17.2.5.6 EMIF Refresh Controller

An SDRAM device requires that each of its rows be refreshed at a minimum required rate. The EMIF can meet this constraint by performing auto refresh cycles at or above this required rate. An auto refresh cycle consists of issuing a PRE command to all banks of the SDRAM device followed by issuing a REFR command. To inform the EMIF of the required rate for performing auto refresh cycles, the RR field of the SDRAM refresh control register (SDRCR) must be programmed. The EMIF will use this value along with two internal counters to automatically perform auto refresh cycles at the required rate. The auto refresh cycles cannot be disabled, even if the EMIF is not interfaced with an SDRAM. The remainder of this section details the EMIF's refresh scheme and provides an example for determining the appropriate value to place in the RR field of SDRCR.

The two counters used to perform auto-refresh cycles are a 13-bit refresh interval counter and a 4-bit refresh backlog counter. At reset and upon writing to the RR field, the refresh interval counter is loaded with the value from RR field and begins decrementing, by one, each EMIF clock cycle. When the refresh interval counter reaches zero, the following actions occur:

- The refresh interval counter is reloaded with the value from the RR field and restarts decrementing.
- The 4-bit refresh backlog counter increments unless it has already reached its maximum value.

The refresh backlog counter records the number of auto refresh cycles that the EMIF currently has outstanding. This counter is decremented by one each time an auto refresh cycle is performed and incremented by one each time the refresh interval counter expires. The refresh backlog counter saturates at the values of 0000b and 1111b. The EMIF uses the refresh backlog counter to determine the urgency with which an auto refresh cycle should be performed. The four levels of urgency are described in [Table 17-12](#). This refresh scheme allows the required refreshes to be performed with minimal impact on access requests.

Table 17-12. Refresh Urgency Levels

| Urgency Level | Refresh Backlog Counter Range | Action Taken |
|-----------------|-------------------------------|--|
| Refresh May | 1-3 | An auto-refresh cycle is performed only if the EMIF has no requests pending and none of the SDRAM banks are open. |
| Refresh Release | 4-7 | An auto-refresh cycle is performed if the EMIF has no requests pending, regardless of whether any SDRAM banks are open. |
| Refresh Need | 8-11 | An auto-refresh cycle is performed at the completion of the current access unless there are read requests pending. |
| Refresh Must | 12-15 | Multiple auto-refresh cycles are performed at the completion of the current access until the Refresh Release urgency level is reached. At that point, the EMIF can begin servicing any new read or write requests. |

17.2.5.6.1 Determining the Appropriate Value for the RR Field

The value that should be programmed into the RR field of SDCR can be calculated by using the frequency of the EMIF_CLK signal ($f_{\text{EMIF_CLK}}$) and the required refresh rate of the SDRAM (f_{Refresh}). The following formula can be used:

$$RR = f_{\text{EMIF_CLK}} / f_{\text{Refresh}}$$

The SDRAM datasheet often communicates the required SDRAM Refresh Rate in terms of the number of REFR commands required in a given time interval. The required SDRAM Refresh Rate in the formula above can therefore be calculated by dividing the number of required cycles per time interval (n_{cycles}) by the time interval given in the datasheet ($t_{\text{Refresh Period}}$):

$$f_{\text{Refresh}} = n_{\text{cycles}} / t_{\text{Refresh Period}}$$

Combining these formulas, the value that should be programmed into the RR field can be computed as:

$$RR = f_{\text{EMIF_CLK}} \times t_{\text{Refresh Period}} / n_{\text{cycles}}$$

The following example illustrates calculating the value of RR. Given that:

- $f_{\text{EMIF_CLK}} = 100 \text{ MHz}$ (frequency of the EMIF clock)
- $t_{\text{Refresh Period}} = 64 \text{ ms}$ (required refresh interval of the SDRAM)
- $n_{\text{cycles}} = 8192$ (number of cycles in a refresh interval for the SDRAM)

RR can be calculated as:

$$RR = 100 \text{ MHz} \times 64 \text{ ms} / 8192$$

$$RR = 781.25$$

$$RR = 782 \text{ cycles} = 30\text{Eh cycles}$$

17.2.5.7 Self-Refresh Mode

The EMIF can be programmed to enter the self-refresh state by setting the SR bit of SDCR to 1. This will cause the EMIF to issue the SLFR command after completing any outstanding SDRAM access requests and clearing the refresh backlog counter by performing one or more auto refresh cycles. This places the attached SDRAM device into self-refresh mode in which it consumes a minimal amount of power while performing its own refresh cycles. The SR bit should be set and cleared using a byte-write to the upper byte of the SDRAM configuration register (SDCR) to avoid triggering the SDRAM initialization sequence.

While in the self-refresh state, the EMIF continues to service asynchronous bank requests and register accesses as normal, with one caveat. The EMIF will not park the data bus following a read to asynchronous memory while in the self-refresh state. Instead, the EMIF tri-states the data bus. Therefore, it is not recommended to perform asynchronous read operations while the EMIF is in the self-refresh state, in order to prevent floating inputs on the data bus. More information about data bus parking can be found in [Section 17.2.7](#).

The EMIF will exit from the self-refresh state if either of the following events occur:

- The SR bit of SDCR is cleared to 0.
- An SDRAM accesses is requested.

The EMIF exits from the self-refresh state by driving EMIF_CKE high and performing an auto refresh cycle.

The attached SDRAM device should also be placed into Self-Refresh Mode when changing the frequency of EMIF_CLK. If the frequency of EMIF_CLK changes while the SDRAM is not in Self-Refresh Mode, Procedure B in [Section 17.2.5.5](#) should be followed to reinitialize the device.

17.2.5.8 Power Down Mode

To support low-power modes, the EMIF can be requested to issue a POWER DOWN command to the SDRAM by setting the PD bit in the SDRAM configuration register (SDCR). When this bit is set, the EMIF will continue normal operation until all outstanding memory access requests have been serviced and the SDRAM refresh backlog (if there is one) has been cleared. At this point the EMIF will enter the power-down state. Upon entering this state, the EMIF will issue a POWER DOWN command (same as a NOP command but driving EMIF_CKE low on the same cycle). The EMIF then maintains EMIF_CKE low until it exits the power-down state.

Since the EMIF services the refresh backlog before it enters the power-down state, all internal banks of the SDRAM are closed (precharged) prior to issuing the POWER DOWN command. Therefore, the EMIF only supports Precharge Power Down. The EMIF does not support Active Power Down, where internal banks of the SDRAM are open (active) before the POWER DOWN command is issued.

During the power-down state, the EMIF services the SDRAM, asynchronous memory, and register accesses as normal, returning to the power-down state upon completion.

The PDWR bit in SDCR indicates whether the EMIF should perform refreshes in power-down state. If the PDWR bit is set, the EMIF exits the power-down state every time the Refresh Must level is set, performs AUTO REFRESH commands to the SDRAM, and returns back to the power-down state. This evenly distributes the refreshes to the SDRAM in power-down state. If the PDWR bit is not set, the EMIF does not perform any refreshes to the SDRAM. Therefore, the data integrity of the SDRAM is not assured upon power down exit if the PDWR bit is not set.

If the PD bit is cleared while in the power-down state, the EMIF will come out of the power-down state. The EMIF:

- Drives EMIF_CKE high.
- Enters its idle state.

17.2.5.9 SDRAM Read Operation

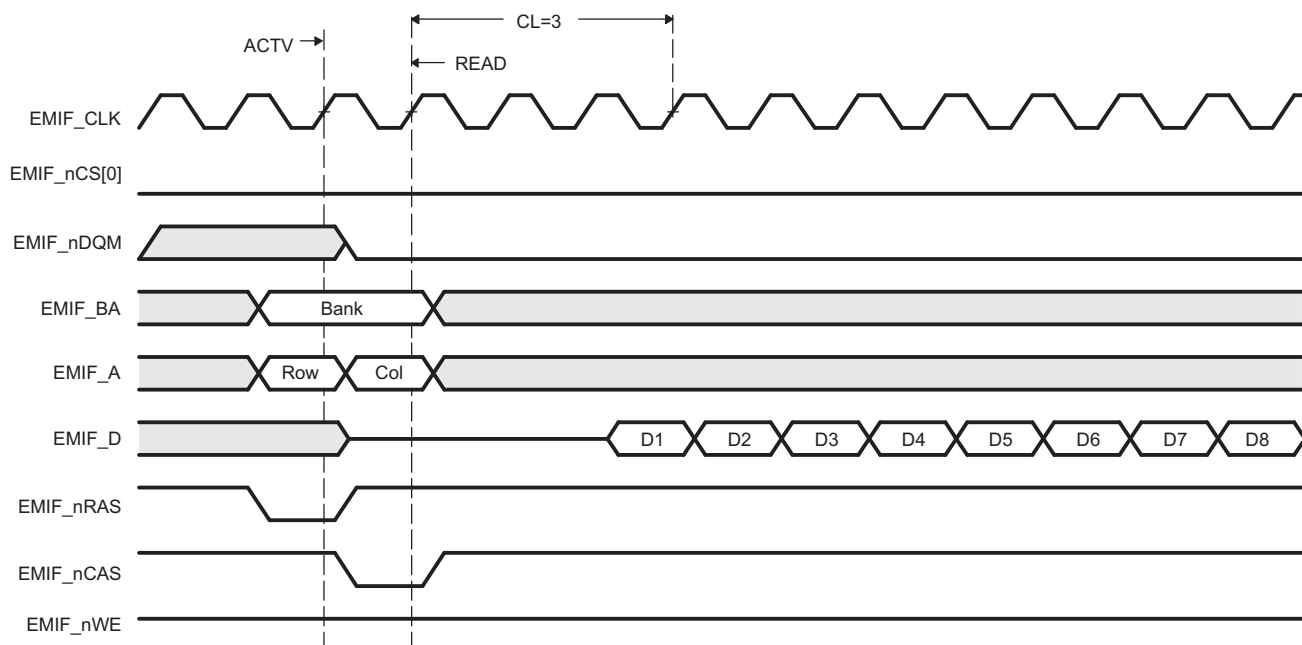

When the EMIF receives a read request to SDRAM from one of the requesters listed in [Section 17.2.2](#), it performs one or more read access cycles. A read access cycle begins with the issuing of the ACTV command to select the desired bank and row of the SDRAM device. After the row has been opened, the EMIF proceeds to issue a READ command while specifying the desired bank and column address. EMIF_A[10] is held low during the READ command to avoid auto-precharging. The READ command signals the SDRAM device to start bursting data from the specified address while the EMIF issues NOP commands. Following a READ command, the CL field of the SDRAM configuration register (SDCR) defines how many delay cycles will be present before the read data appears on the data bus. This is referred to as the CAS latency.

[Figure 17-5](#) shows the signal waveforms for a basic SDRAM read operation in which a burst of data is read from a single page. When the EMIF SDRAM interface is configured to 16 bit by setting the NM bit of the SDRAM configuration register (SDCR) to 1, a burst size of eight is used. [Figure 17-5](#) shows a burst size of eight.

The EMIF will truncate a series of bursting data if the remaining addresses of the burst are not required to complete the request. The EMIF can truncate the burst in three ways:

- By issuing another READ to the same page in the same bank.
- By issuing a PRE command in order to prepare for accessing a different page of the same bank.
- By issuing a BT command in order to prepare for accessing a page in a different bank.

Figure 17-5. Timing Waveform for Basic SDRAM Read Operation

Several other pins are also active during a read access. The EMIF_nDQM[1:0] pins are driven low during the READ commands and are kept low during the NOP commands that correspond to the burst request. The state of the other EMIF pins during each command can be found in [Table 17-5](#).

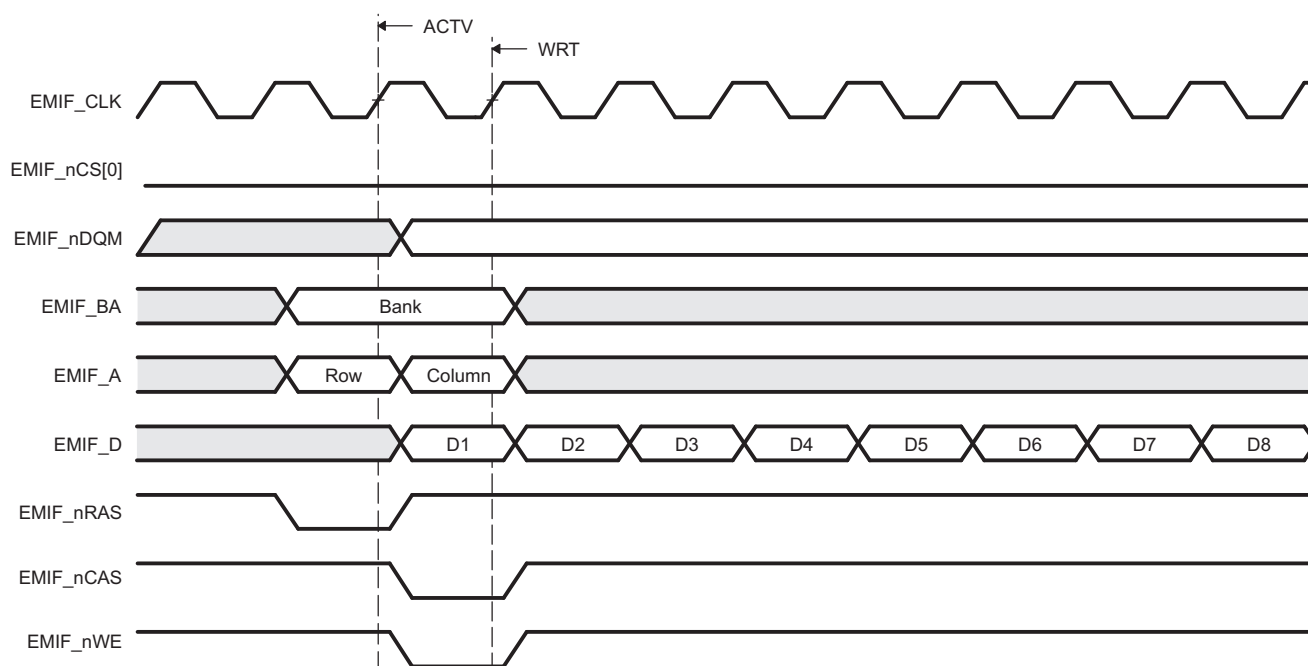

The EMIF schedules its commands based on the timing information that is provided to it in the SDRAM timing register (SDTIMR). The values for the timing parameters in this register should be chosen to satisfy the timing requirements listed in the SDRAM datasheet. The EMIF uses this timing information to avoid violating any timing constraints related to issuing commands. This is commonly accomplished by inserting NOP commands between various commands during an access. Refer to the register description of SDTIMR in [Section 17.3.6](#) for more details on the various timing parameters.

17.2.5.10 SDRAM Write Operations

When the EMIF receives a write request to SDRAM from one of the requesters listed in [Section 17.2.2](#), it performs one or more write-access cycles. A write-access cycle begins with the issuing of the ACTV command to select the desired bank and row of the SDRAM device. After the row has been opened, the EMIF proceeds to issue a WRT command while specifying the desired bank and column address. EMIF_A[10] is held low during the WRT command to avoid auto-precharging. The WRT command signals the SDRAM device to start writing a burst of data to the specified address while the EMIF issues NOP commands. The associated write data will be placed on the data bus in the cycle concurrent with the WRT command and with subsequent burst continuation NOP commands.

[Figure 17-6](#) shows the signal waveforms for a basic SDRAM write operation in which a burst of data is read from a single page. When the EMIF SDRAM interface is configured to 16-bit by setting the NM bit of the SDRAM configuration register (SDCR) to 1, a burst size of eight is used. [Figure 17-6](#) shows a burst size of eight.

Figure 17-6. Timing Waveform for Basic SDRAM Write Operation

The EMIF will truncate a series of bursting data if the remaining addresses of the burst are not part of the write request. The EMIF can truncate the burst in three ways:

- By issuing another WRT to the same page
- By issuing a PRE command in order to prepare for accessing a different page of the same bank
- By issuing a BT command in order to prepare for accessing a page in a different bank

Several other pins are also active during a write access. The EMIF_nDQM[1:0] pins are driven to select which bytes of the data word will be written to the SDRAM device. They are also used to mask out entire undesired data words during a burst access. The state of the other EMIF pins during each command can be found in [Table 17-5](#).

The EMIF schedules its commands based on the timing information that is provided to it in the SDRAM timing register (SDTIMR). The values for the timing parameters in this register should be chosen to satisfy the timing requirements listed in the SDRAM datasheet. The EMIF uses this timing information to avoid violating any timing constraints related to issuing commands. This is commonly accomplished by inserting NOP commands during various cycles of an access. Refer to the register description of SDTIMR in [Section 17.3.6](#) for more details on the various timing parameters.

17.2.5.11 Mapping from Logical Address to EMIF Pins

When the EMIF receives an SDRAM access request, it must convert the address of the access into the appropriate signals to send to the SDRAM device. The details of this address mapping are shown in [Table 17-13](#) for 16-bit operation. Using the settings of the IBANK and PAGESIZE fields of the SDRAM configuration register (SDCR), the EMIF determines which bits of the logical address will be mapped to the SDRAM row, column, and bank addresses.

As the logical address is incremented by one halfword (16-bit operation), the column address is likewise incremented by one until a page boundary is reached. When the logical address increments across a page boundary, the EMIF moves into the same page in the next bank of the attached device by incrementing the bank address EMIF_BA and resetting the column address. The page in the previous bank is left open until it is necessary to close it. This method of traversal through the SDRAM banks helps maximize the number of open banks inside of the SDRAM and results in an efficient use of the device. There is no limitation on the number of banks that can be open at one time, but only one page within a bank can be open at a time.

The EMIF uses the EMIF_nDQM[1:0] pins during a WRT command to mask out selected bytes or entire words. The EMIF_nDQM[1:0] pins are always low during a READ command.

Table 17-13. Mapping from Logical Address to EMIF Pins for 16-bit SDRAM

| IBANK | PAGESIZE | Logical Address | | | | | |
|-------|----------|-----------------|----------------|----------------|----------------|----------------|--------------|
| | | 12 | 11 | 10 | 9 | 8:1 | 0 |
| 0 | 0 | Row Address | | | | Column Address | EMIF_nDQM[0] |
| 1 | 0 | Row Address | | | EMIF_BA[0] | Column Address | EMIF_nDQM[0] |
| 2 | 0 | Row Address | | EMIF_BA[1:0] | | Column Address | EMIF_nDQM[0] |
| 0 | 1 | Row Address | | | Column Address | | EMIF_nDQM[0] |
| 1 | 1 | Row Address | | EMIF_BA[0] | Column Address | | EMIF_nDQM[0] |
| 2 | 1 | Row Address | EMIF_BA[1:0] | | Column Address | | EMIF_nDQM[0] |
| 0 | 2 | Row Address | | Column Address | | | EMIF_nDQM[0] |
| 1 | 2 | Row Address | EMIF_BA[0] | Column Address | | | EMIF_nDQM[0] |
| 2 | 2 | EMIF_BA[1:0] | | Column Address | | | EMIF_nDQM[0] |
| 0 | 3 | Row Address | Column Address | | | | EMIF_nDQM[0] |
| 1 | 3 | EMIF_BA[0] | Column Address | | | | EMIF_nDQM[0] |
| 2 | 3 | EMIF_BA[0] | Column Address | | | | EMIF_nDQM[0] |

NOTE: The upper bit of the Row Address is used only when addressing 256-Mbit and 512-Mbit SDRAM memories.

17.2.6 Asynchronous Controller and Interface

The EMIF easily interfaces to a variety of asynchronous devices including NOR Flash, NAND Flash, and SRAM. It can be operated in two major modes (see [Table 17-14](#)):

- Normal Mode
- Select Strobe Mode

Table 17-14. Normal Mode vs. Select Strobe Mode

| Mode | Function of EMIF_nDQM pins | Operation of EMIF_nCS[4:2] |
|--------------------|----------------------------|---|
| Normal Mode | Byte enables | Active during the entire asynchronous access cycle |
| Select Strobe Mode | Byte enables | Active only during the strobe period of an access cycle |

The first mode of operation is Normal Mode, in which the EMIF_nDQM pins of the EMIF function as byte enables. In this mode, the EMIF_nCS[4:2] pins behaves as typical chip select signals, remaining active for the duration of the asynchronous access. See [Section 17.2.6.1](#) for an example interface with multiple 8-bit devices.

The second mode of operation is Select Strobe Mode, in which the EMIF_nCS[4:2] pins act as a strobe, active only during the strobe period of an access. In this mode, the EMIF_nDQM pins of the EMIF function as standard byte enables for reads and writes. A summary of the differences between the two modes of operation are shown in [Table 17-14](#). Refer to [Section 17.2.6.4](#) for the details of asynchronous operations in Normal Mode, and to [Section 17.2.6.5](#) for the details of asynchronous operations in Select Strobe Mode. The EMIF hardware defaults to Normal Mode, but can be manually switched to Select Strobe Mode by setting the SS bit in the asynchronous m ($m = 1, 2, 3$, or 4) configuration register (CE n CFG) ($n = 2, 3$, or 4). Throughout the chapter, m can hold the values 1, 2, 3 or 4; and n can hold the values 2, 3, or 4.

The EMIF also provides configurable cycle timing parameters and an Extended Wait Mode that allows the connected device to extend the strobe period of an access cycle. The following sections describe the features related to interfacing with external asynchronous devices.

17.2.6.1 Interfacing to Asynchronous Memory

[Figure 17-7](#) shows the EMIF's external pins used in interfacing with an asynchronous device. In EMIF_nCS[n], $n = 2, 3$, or 4 .

Figure 17-7. EMIF Asynchronous Interface

Of special note is the connection between the EMIF and the external device's address bus. The EMIF address pin EMIF_A[0] always provides the least-significant bit of a 32-bit word address. Therefore, when interfacing to a 16-bit or 8-bit asynchronous device, the EMIF_BA[1] and EMIF_BA[0] pins provide the least-significant bits of the halfword or byte address, respectively. Additionally, when the EMIF interfaces to a 16-bit asynchronous device, the EMIF_BA[0] pin can serve as the upper address line EMIF_A[12]. [Figure 17-8](#) and [Figure 17-9](#) show the mapping between the EMIF and the connected device's data and address pins for various programmed data bus widths. The data bus width may be configured in the asynchronous *n* configuration register (CE_nCFG).

[Figure 17-9](#) shows a common interface between the EMIF and external asynchronous memory. [Figure 17-9](#) shows an interface between the EMIF and an external memory with byte enables. The EMIF should be operated in either Normal Mode or Select Strobe Mode when using this interface, so that the EMIF_nDQM signals operate as byte enables.

Figure 17-8. EMIF to 8-bit/16-bit Memory Interface

a) EMIF to 8-bit memory interface

b) EMIF to 16-bit memory interface

Figure 17-9. Common Asynchronous Interface

17.2.6.2 Accessing Larger Asynchronous Memories

The device has 13 dedicated EMIF address lines. If a device such as a large asynchronous flash needs to be attached to the EMIF, then GPIO pins may be used to control the flash device's upper address lines.

17.2.6.3 Configuring the EMIF for Asynchronous Accesses

The operation of the EMIF's asynchronous interface can be configured by programming the appropriate register fields. The reset value and bit position for each register field can be found in [Section 17.3](#). The following tables list the register fields that can be programmed and describe the purpose of each field. These registers can be programmed prior to accessing the external memory, and the transfer following a write to these registers will use the new configuration.

Table 17-15. Description of the Asynchronous *m* Configuration Register (CE_nCFG)

| Parameter | Description |
|-------------------|---|
| SS | Select Strobe mode. This bit selects the EMIF's mode of operation in the following way: <ul style="list-style-type: none"> SS = 0 selects Normal Mode <ul style="list-style-type: none"> EMIF_nDQM pins function as byte enables EMIF_nCS[4:2] active for duration of access SS = 1 selects Select Strobe Mode <ul style="list-style-type: none"> EMIF_nDQM pins function as byte enables EMIF_nCS[4:2] acts as a strobe. |
| EW | Extended Wait Mode enable. <ul style="list-style-type: none"> EW = 0 disables Extended Wait Mode EW = 1 enables Extended Wait Mode When set to 1, the EMIF enables its Extended Wait Mode in which the strobe width of an access cycle can be extended in response to the assertion of the EMIF_nWAIT pin. The WP _n bit in the asynchronous wait cycle configuration register (AWCC) controls to polarity of EMIF_nWAIT pin. See Section 17.2.6.6 for more details on this mode of operation. |
| W_SETUP/R_SETUP | Read/Write setup widths. These fields define the number of EMIF clock cycles of setup time for the address pins (EMIF_A and EMIF_BA), byte enables (EMIF_nDQM), and asynchronous chip enable (EMIF_nCS[4:2]) before the read strobe pin (EMIF_nOE) or write strobe pin (EMIF_nWE) falls, minus one cycle. For writes, the W_SETUP field also defines the setup time for the data pins (EMIF_D). Refer to the datasheet of the external asynchronous device to determine the appropriate setting for this field. |
| W_STROBE/R_STROBE | Read/Write strobe widths. These fields define the number of EMIF clock cycles between the falling and rising of the read strobe pin (EMIF_nOE) or write strobe pin (EMIF_nWE), minus one cycle. If Extended Wait Mode is enabled by setting the EW field in the asynchronous <i>n</i> configuration register (CE _n CFG), these fields must be set to a value greater than zero. Refer to the datasheet of the external asynchronous device to determine the appropriate setting for this field. |
| W_HOLD/R_HOLD | Read/Write hold widths. These fields define the number of EMIF clock cycles of hold time for the address pins (EMIF_A and EMIF_BA), byte enables (EMIF_nDQM), and asynchronous chip enable (EMIF_nCS[4:2]) after the read strobe pin (EMIF_nOE) or write strobe pin (EMIF_nWE) rises, minus one cycle. For writes, the W_HOLD field also defines the hold time for the data pins (EMIF_D). Refer to the datasheet of the external asynchronous device to determine the appropriate setting for this field. |
| TA | Minimum turnaround time. This field defines the minimum number of EMIF clock cycles between asynchronous reads and writes, minus one cycle. The purpose of this feature is to avoid contention on the bus. The value written to this field also determines the number of cycles that will be inserted between asynchronous accesses and SDRAM accesses. Refer to the datasheet of the external asynchronous device to determine the appropriate setting for this field. |

Table 17-15. Description of the Asynchronous *m* Configuration Register (CE_nCFG) (continued)

| Parameter | Description |
|-----------|---|
| ASIZE | <p>Asynchronous Device Bus Width. This field determines the data bus width of the asynchronous interface in the following way:</p> <ul style="list-style-type: none"> ASIZE = 0 selects an 8-bit bus ASIZE = 1 selects a 16-bit bus <p>The configuration of ASIZE determines the function of the EMIF_A and EMIF_BA pins as described in Section 17.2.6.1. This field also determines the number of external accesses required to fulfill a request generated by one of the sources mentioned in Section 17.2.2. For example, a request for a 32-bit word would require four external access when ASIZE = 0. Refer to the datasheet of the external asynchronous device to determine the appropriate setting for this field.</p> |

Table 17-16. Description of the Asynchronous Wait Cycle Configuration Register (AWCC)

| Parameter | Description |
|-----------------|--|
| WP _n | <p>EM_WAIT Polarity.</p> <ul style="list-style-type: none"> WP_n = 0 selects active-low polarity WP_n = 1 selects active-high polarity <p>When set to 1, the EMIF will wait if the EMIF_nWAIT pin is high. When cleared to 0, the EMIF will wait if the EMIF_nWAIT pin is low. The EMIF must have the Extended Wait Mode enabled for the EMIF_nWAIT pin to affect the width of the strobe period.</p> |
| MAX_EXT_WAIT | <p>Maximum Extended Wait Cycles. This field configures the number of EMIF clock cycles the EMIF will wait for the EMIF_nWAIT pin to be deactivated during the strobe period of an access cycle. The maximum number of EMIF clock cycles it will wait is determined by the following formula: Maximum Extended Wait Cycles = (MAX_EXT_WAIT + 1) × 16 If the EMIF_nWAIT pin is not deactivated within the time specified by this field, the EMIF resumes the access cycle, registering whatever data is on the bus and proceeding to the hold period of the access cycle. This situation is referred to as an Asynchronous Timeout. An Asynchronous Timeout generates an interrupt, if it has been enabled in the EMIF interrupt mask set register (INTMSKSET). Refer to Section 17.2.9.1 for more information about the EMIF interrupts.</p> |

Table 17-17. Description of the EMIF Interrupt Mask Set Register (INTMSKSET)

| Parameter | Description |
|-------------|---|
| WR_MASK_SET | <p>Wait Rise Mask Set. Writing a 1 enables an interrupt to be generated when a rising edge on EMIF_nWAIT occurs while in NAND Flash Mode</p> |
| AT_MASK_SET | <p>Asynchronous Timeout Mask Set. Writing a 1 to this bit enables an interrupt to be generated when an Asynchronous Timeout occurs.</p> |

Table 17-18. Description of the EMIF Interrupt Mast Clear Register (INTMSKCLR)

| Parameter | Description |
|-------------|---|
| WR_MASK_CLR | <p>Wait Rise Mask Clear. Writing a 1 to this bit disables the interrupt, clearing the WR_MASK_SET bit in the EMIF interrupt mask set register (INTMSKSET).</p> |
| AT_MASK_CLR | <p>Asynchronous Timeout Mask Clear. Writing a 1 to this bit prevents an interrupt from being generated when an Asynchronous Timeout occurs.</p> |

17.2.6.4 Read and Write Operations in Normal Mode

Normal Mode is the asynchronous interface's default mode of operation. It is selected when the SS bit in the asynchronous *n* configuration register (CE_nCFG) is cleared to 0. In this mode, the EMIF_nDQM pins operate as byte enables. [Section 17.2.6.4.1](#) and [Section 17.2.6.4.2](#) explain the details of read and write operations while in Normal Mode.

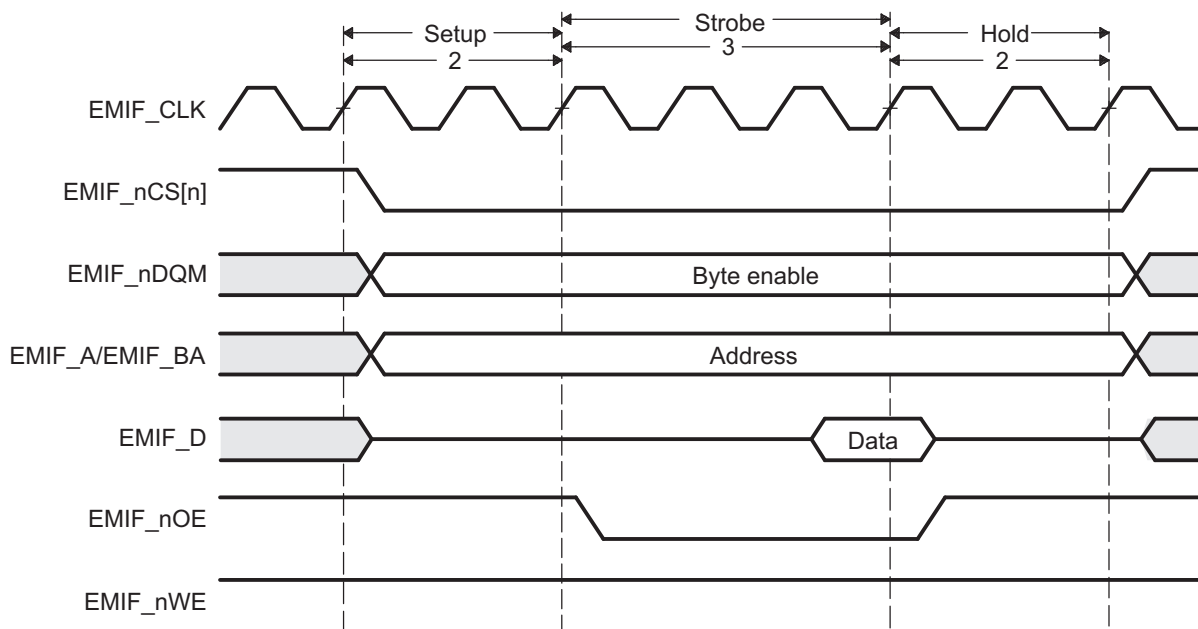

17.2.6.4.1 Asynchronous Read Operations (Normal Mode)

NOTE: During an entire asynchronous read operation, the EMIF_nWE pin is driven high.

An asynchronous read is performed when any of the requesters mentioned in [Section 17.2.2](#) request a read from the attached asynchronous memory. After the request is received, a read operation is initiated once it becomes the EMIF's highest priority task, according to the priority scheme detailed in [Section 17.2.13](#). In the event that the read request cannot be serviced by a single access cycle to the external device, multiple access cycles will be performed by the EMIF until the entire request is fulfilled. The details of an asynchronous read operation in Normal Mode are described in [Table 17-19](#). Also, [Figure 17-10](#) shows an example timing diagram of a basic read operation.

Table 17-19. Asynchronous Read Operation in Normal Mode

| Time Interval | Pin Activity in Normal Mode |
|---------------------------|--|
| Turn-around period | <p>Once the read operation becomes the highest priority task for the EMIF, the EMIF waits for the programmed number of turn-around cycles before proceeding to the setup period of the operation. The number of wait cycles is taken directly from the TA field of the asynchronous <i>n</i> configuration register (CE_nCFG). There are two exceptions to this rule:</p> <ul style="list-style-type: none"> If the current read operation was directly preceded by another read operation, no turnaround cycles are inserted. If the current read operation was directly preceded by a write operation and the TA field has been cleared to 0, one turn-around cycle will be inserted. <p>After the EMIF has waited for the turnaround cycles to complete, it again checks to make sure that the read operation is still its highest priority task. If so, the EMIF proceeds to the setup period of the operation. If it is no longer the highest priority task, the EMIF terminates the operation.</p> |
| Start of the setup period | <p>The following actions occur at the start of the setup period:</p> <ul style="list-style-type: none"> The setup, strobe, and hold values are set according to the R_SETUP, R_STROBE, and R_HOLD values in CE_nCFG. The address pins EMIF_A and EMIF_BA become valid and carry the values described in Section 17.2.6.1. EMIF_nCS[4:2] falls to enable the external device (if not already low from a previous operation) |
| Strobe period | <p>The following actions occur during the strobe period of a read operation:</p> <ol style="list-style-type: none"> EMIF_nOE falls at the start of the strobe period On the rising edge of the clock which is concurrent with the end of the strobe period: <ul style="list-style-type: none"> EMIF_nOE rises The data on the EMIF_D bus is sampled by the EMIF. <p>In Figure 17-10, EMIF_nWAIT is inactive. If EMIF_nWAIT is instead activated, the strobe period can be extended by the external device to give it more time to provide the data. Section 17.2.6.6 contains more details on using the EMIF_nWAIT pin.</p> |
| End of the hold period | <p>At the end of the hold period:</p> <ul style="list-style-type: none"> The address pins EMIF_A and EMIF_BA become invalid EMIF_nCS[4:2] rises (if no more operations are required to complete the current request) <p>EMIF may be required to issue additional read operations to a device with a small data bus width in order to complete an entire word access. In this case, the EMIF immediately re-enters the setup period to begin another operation without incurring the turn-round cycle delay. The setup, strobe, and hold values are not updated in this case. If the entire word access has been completed, the EMIF returns to its previous state unless another asynchronous request has been submitted and is currently the highest priority task. If this is the case, the EMIF instead enters directly into the turnaround period for the pending read or write operation.</p> |

Figure 17-10. Timing Waveform of an Asynchronous Read Cycle in Normal Mode

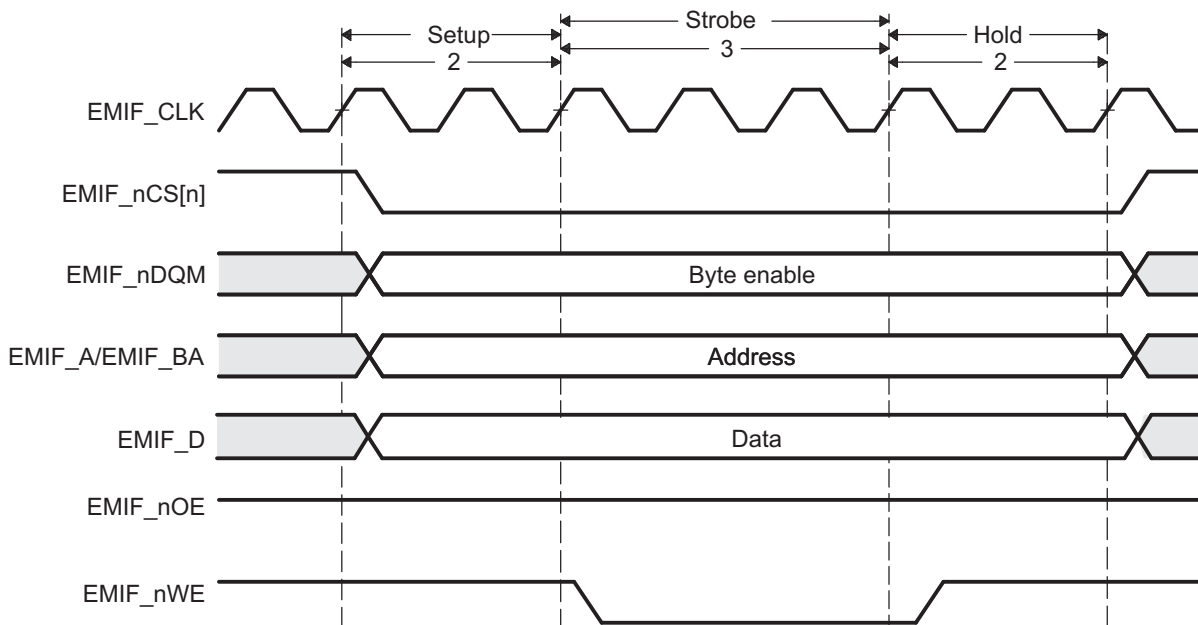

17.2.6.4.2 Asynchronous Write Operations (Normal Mode)

NOTE: During an entire asynchronous write operation, the EMIF_nOE pin is driven high.

An asynchronous write is performed when any of the requesters mentioned in [Section 17.2.2](#) request a write to memory in the asynchronous bank of the EMIF. After the request is received, a write operation is initiated once it becomes the EMIF's highest priority task, according to the priority scheme detailed in [Section 17.2.13](#). In the event that the write request cannot be serviced by a single access cycle to the external device, multiple access cycles will be performed by the EMIF until the entire request is fulfilled. The details of an asynchronous write operation in Normal Mode are described in [Table 17-20](#). Also, [Figure 17-11](#) shows an example timing diagram of a basic write operation.

Table 17-20. Asynchronous Write Operation in Normal Mode

| Time Interval | Pin Activity in Normal Mode |
|---------------------------|---|
| Turnaround period | <p>Once the write operation becomes the highest priority task for the EMIF, the EMIF waits for the programmed number of turn-around cycles before proceeding to the setup period of the operation. The number of wait cycles is taken directly from the TA field of the asynchronous <i>n</i> configuration register (CE_nCFG). There are two exceptions to this rule:</p> <ul style="list-style-type: none"> • If the current write operation was directly preceded by another write operation, no turn-around cycles are inserted. • If the current write operation was directly preceded by a read operation and the TA field has been cleared to 0, one turnaround cycle will be inserted. <p>After the EMIF has waited for the turn-around cycles to complete, it again checks to make sure that the write operation is still its highest priority task. If so, the EMIF proceeds to the setup period of the operation. If it is no longer the highest priority task, the EMIF terminates the operation.</p> |

| End of the hold period | <p>At the end of the hold period:</p> <ul style="list-style-type: none"> • The address pins EMIF_A and EMIF_BA become invalid • The data pins become invalid • EMIF_nCS[n] (n = 2, 3, or 4) rises (if no more operations are required to complete the current request) <p>The EMIF may be required to issue additional write operations to a device with a small data bus width in order to complete an entire word access. In this case, the EMIF immediately re-enters the setup period to begin another operation without incurring the turnaround cycle delay. The setup, strobe, and hold values are not updated in this case. If the entire word access has been completed, the EMIF returns to its previous state unless another asynchronous request has been submitted and is currently the highest priority task. If this is the case, the EMIF instead enters directly into the turnaround period for the pending read or write operation.</p> |

Figure 17-11. Timing Waveform of an Asynchronous Write Cycle in Normal Mode

17.2.6.5 Read and Write Operation in Select Strobe Mode

Select Strobe Mode is the EMIF's second mode of operation. It is selected when the SS bit of the asynchronous n configuration register (CE n CFG) is set to 1. In this mode, the EMIF_nDQM pins operate as byte enables and the EMIF_nCS[n] ($n = 2, 3, \text{ or } 4$) pin is only active during the strobe period of an access cycle. [Section 17.2.6.4.1](#) and [Section 17.2.6.4.2](#) explain the details of read and write operations while in Select Strobe Mode.

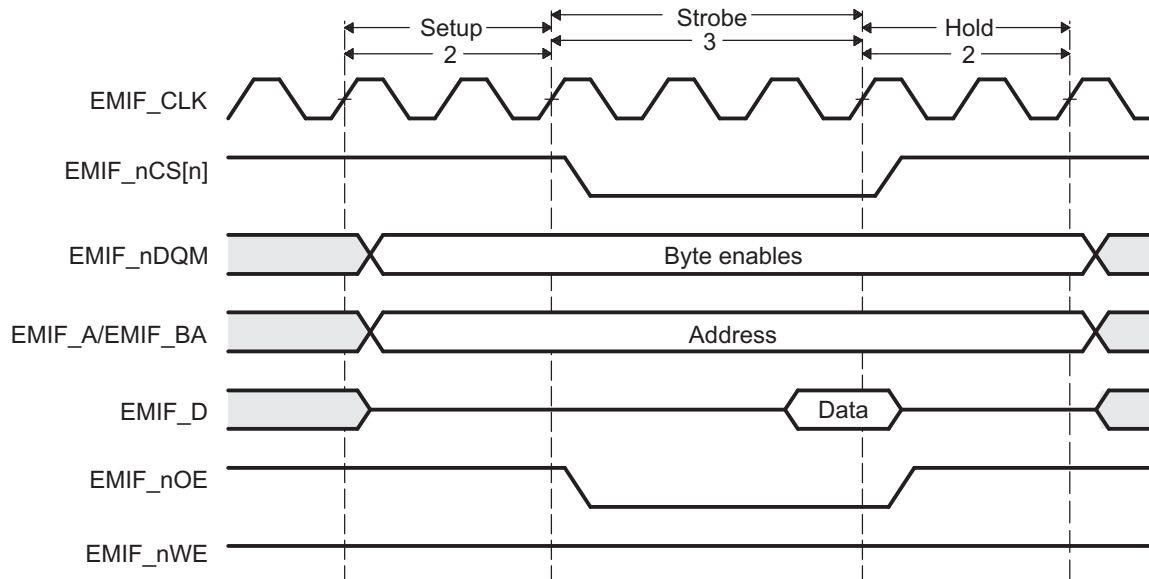

17.2.6.5.1 Asynchronous Read Operations (Select Strobe Mode)

NOTE: During the entirety of an asynchronous read operation, the EMIF_nWE pin is driven high.

An asynchronous read is performed when any of the requesters mentioned in [Section 17.2.2](#) request a read from the attached asynchronous memory. After the request is received, a read operation is initiated once it becomes the EMIF's highest priority task, according to the priority scheme detailed in [Section 17.2.13](#). In the event that the read request cannot be serviced by a single access cycle to the external device, multiple access cycles will be performed by the EMIF until the entire request is fulfilled. The details of an asynchronous read operation in Select Strobe Mode are described in [Table 17-21](#). Also, [Figure 17-12](#) shows an example timing diagram of a basic read operation.

Table 17-21. Asynchronous Read Operation in Select Strobe Mode

| Time Interval | Pin Activity in Select Strobe Mode |
|---------------------------|--|
| Turnaround period | <p>Once the read operation becomes the highest priority task for the EMIF, the EMIF waits for the programmed number of turn-around cycles before proceeding to the setup period of the operation. The number of wait cycles is taken directly from the TA field of the asynchronous n configuration register (CEnCFG). There are two exceptions to this rule:</p> <ul style="list-style-type: none"> If the current read operation was directly preceded by another read operation, no turn-around cycles are inserted. Figure 17-12. Timing Waveform of an Asynchronous Read Cycle in Select Strobe Mode

17.2.6.5.2 Asynchronous Write Operations (Select Strobe Mode)

NOTE: During the entirety of an asynchronous write operation, the EMIF_nOE pin is driven high.

An asynchronous write is performed when any of the requesters mentioned in [Section 17.2.2](#) request a write to memory in the asynchronous bank of the EMIF. After the request is received, a write operation is initiated once it becomes the EMIF's highest priority task, according to the priority scheme detailed in [Section 17.2.13](#). In the event that the write request cannot be serviced by a single access cycle to the external device, multiple access cycles will be performed by the EMIF until the entire request is fulfilled. The details of an asynchronous write operation in Select Strobe Mode are described in [Table 17-22](#). Also, [Figure 17-13](#) shows an example timing diagram of a basic write operation.

Table 17-22. Asynchronous Write Operation in Select Strobe Mode

| Time Interval | Pin Activity in Select Strobe Mode |
|---------------------------|---|
| Turnaround period | <p>Once the write operation becomes the highest priority task for the EMIF, the EMIF waits for the programmed number of turnaround cycles before proceeding to the setup period of the operation. The number of wait cycles is taken directly from the TA field of the asynchronous <i>n</i> configuration register (CE_nCFG). There are two exceptions to this rule:</p> <ul style="list-style-type: none"> • If the current write operation was directly preceded by another write operation, no turn-around cycles are inserted. • If the current write operation was directly preceded by a read operation and the TA field has been cleared to 0, one turnaround cycle will be inserted. <p>After the EMIF has waited for the turnaround cycles to complete, it again checks to make sure that the write operation is still its highest priority task. If so, the EMIF proceeds to the setup period of the operation. If it is no longer the highest priority task, the EMIF terminates the operation.</p> |
| Start of the setup period | <p>The following actions occur at the start of the setup period:</p> <ul style="list-style-type: none"> • The setup, strobe, and hold values are set according to the W_SETUP, W_STROBE, and W_HOLD values in CE_nCFG. • The address pins EMIF_A and EMIF_BA and the data pins EMIF_D become valid. The EMIF_A and EMIF_BA pins carry the values described in Section 17.2.6.1. • The EMIF_nDQM pins become active as byte enables. |
| Strobe period | <p>The following actions occur at the start of the strobe period of a write operation:</p> <ul style="list-style-type: none"> • EMIF_nCS[n] (n = 2, 3, or 4) and EMIF_nWE fall <p>The following actions occur on the rising edge of the clock which is concurrent with the end of the strobe period:</p> <ul style="list-style-type: none"> • EMIF_nCS[n] (n = 2, 3, or 4) and EMIF_nWE rise <p>In Figure 17-13, EMIF_nWAIT is inactive. If EMIF_nWAIT is instead activated, the strobe period can be extended by the external device to give it more time to accept the data. Section 17.2.6.6 contains more details on using the EMIF_nWAIT pin.</p> |
| End of the hold period | <p>At the end of the hold period:</p> <ul style="list-style-type: none"> • The address pins EMIF_A and EMIF_BA become invalid • The data pins become invalid • The EMIF_nDQM pins become invalid <p>The EMIF may be required to issue additional write operations to a device with a small data bus width in order to complete an entire word access. In this case, the EMIF immediately re-enters the setup period to begin another operation without incurring the turnaround cycle delay. The setup, strobe, and hold values are not updated in this case. If the entire word access has been completed, the EMIF returns to its previous state unless another asynchronous request has been submitted and is currently the highest priority task. If this is the case, the EMIF instead enters directly into the turn-around period for the pending read or write operation.</p> |

Figure 17-13. Timing Waveform of an Asynchronous Write Cycle in Select Strobe Mode

17.2.6.6 Extended Wait Mode and the EMIF_nWAIT Pin

The EMIF supports the Extend Wait Mode. This is a mode in which the external asynchronous device may assert control over the length of the strobe period. The Extended Wait Mode can be entered by setting the EW bit in the asynchronous n configuration register (CENCFG) ($n = 2, 3, \text{ or } 4$). When this bit is set, the EMIF monitors the EMIF_nWAIT pin to determine if the attached device wishes to extend the strobe period of the current access cycle beyond the programmed number of clock cycles.

When the EMIF detects that the EMIF_nWAIT pin has been asserted, it will begin inserting extra strobe cycles into the operation until the EMIF_nWAIT pin is deactivated by the external device. The EMIF will then return to the last cycle of the programmed strobe period and the operation will proceed as usual from this point. Please refer to the device data manual for details on the timing requirements of the EMIF_nWAIT signal.

The EMIF_nWAIT pin cannot be used to extend the strobe period indefinitely. The programmable MAX_EXT_WAIT field in the asynchronous wait cycle configuration register (AWCC) determines the maximum number of EMIF_CLK cycles the strobe period may be extended beyond the programmed length. When the counter expires, the EMIF proceeds to the hold period of the operation regardless of the state of the EMIF_nWAIT pin. The EMIF can also generate an interrupt upon expiration of this counter. See [Section 17.2.9.1](#) for details on enabling this interrupt.

For the EMIF to function properly in the Extended Wait mode, the WP n bit of AWCC must be programmed to match the polarity of the EMIF_nWAIT pin. In its reset state of 1, the EMIF will insert wait cycles when the EMIF_nWAIT pin is sampled high. When set to 0, the EMIF will insert wait cycles only when EMIF_nWAIT is sampled low. This programmability allows for a glueless connection to larger variety of asynchronous devices.

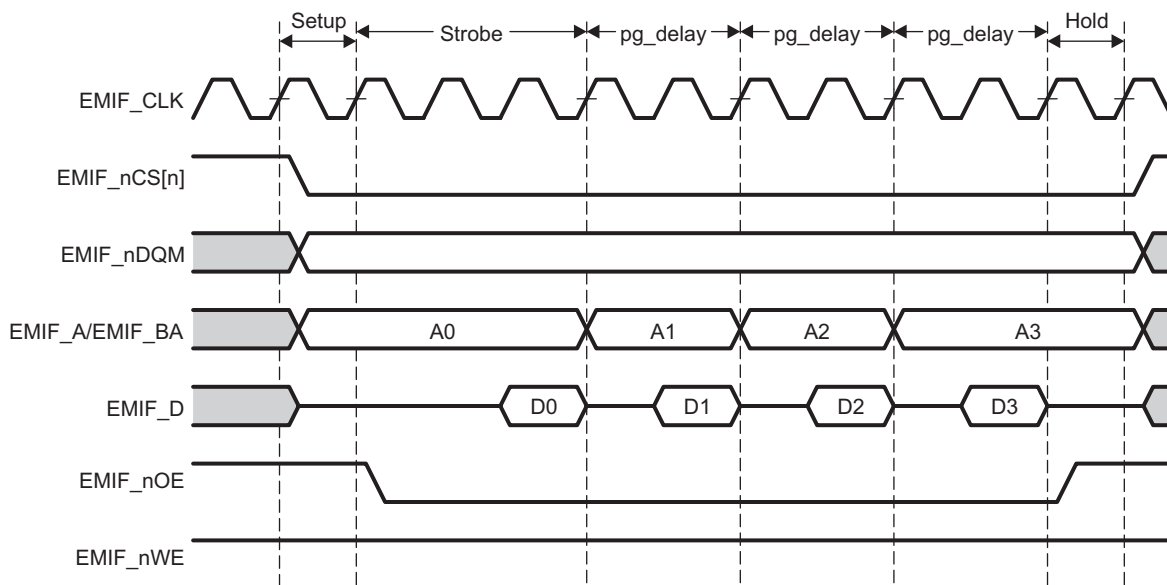

Finally, a restriction is placed on the strobe period timing parameters when operating in Extended Wait mode. Specifically, the sum of the W_SETUP and W_STROBE fields must be greater than 4, and the sum of the R_SETUP and R_STROBE fields must be greater than 4 for the EMIF to recognize the EMIF_nWAIT pin has been asserted. The W_SETUP, W_STROBE, R_SETUP, and R_STROBE fields are in CENCFG.

17.2.6.7 NOR Flash Page Mode

EMIF supports Page mode reads for NOR Flash on its asynchronous memory chip selects. This mode can be enabled by writing a 1 to the $CS_n_PG_MD_EN$ ($n = 2, 3, \text{ or } 4$) field in the Page Mode Control register for the chip select in consideration. Whenever Page Mode for reads is enabled for a particular chip select, the page size for the device connected must also be programmed in the $CS_n_PG_SIZE$ field of the Page Mode Control register. The address change to valid read data available timing must be programmed in the $CS_n_PG_DEL$ field of the Page Control register. All other asynchronous memory timings must be programmed in the asynchronous configuration register (CE n CFG). See [Figure 17-14](#) for read in asynchronous page mode.

NOTE: The Extended Wait mode and the Select Strobe mode must be disabled when using the asynchronous interface in Page mode.

Figure 17-14. Asynchronous Read in Page Mode

17.2.7 Data Bus Parking

The EMIF always drives the data bus to the previous write data value when it is idle. This feature is called data bus parking. Only when the EMIF issues a read command to the external memory does it stop driving the data bus. After the EMIF latches the last read data, it immediately parks the data bus again.

The one exception to this behavior occurs after performing an asynchronous read operation while the EMIF is in the self-refresh state. In this situation, the read operation is not followed by the EMIF parking the data bus. Instead, the EMIF tri-states the data bus. Therefore, it is not recommended to perform asynchronous read operations while the EMIF is in the self-refresh state, in order to prevent floating inputs on the data bus. External pull-ups, such as 10kΩ resistors, should be placed on the 16 EMIF data bus pins (which do not have internal pull-ups) if it is required to perform reads in this situation. The precise resistor value should be chosen so that the worst case combined off-state leakage currents do not cause the voltage levels on the associated pins to drop below the high-level input voltage requirement.

For information about the self-refresh state, see [Section 17.2.5.7](#).

17.2.8 Reset and Initialization Considerations

The EMIF memory controller has two active-low reset signals, CHIP_RST_n and MOD_G_RST_n. Both these reset signals are driven by the device system reset signal. This device does not offer the flexibility to reset just the EMIF state machine without also resetting the EMIF controller's memory-mapped registers. As soon as the device system reset is released (driven High), the EMIF memory controller immediately begins its initialization sequence. Command and data stored in the EMIF memory controller FIFOs are lost. Refer the Architecture chapter of the technical reference manual (TRM) for more information on conditions that can cause a device system reset to be asserted.

When system reset is released, the EMIF automatically begins running the SDRAM initialization sequence described in [Section 17.2.5.4](#). Even though the initialization procedure is automatic, a special procedure, found in [Section 17.2.5.5](#) must still be followed.

17.2.9 Interrupt Support

The EMIF supports a single interrupt to the CPU. [Section 17.2.9.1](#) details the generation and internal masking of EMIF interrupts.

17.2.9.1 Interrupt Events

There are three conditions that may cause the EMIF to generate an interrupt to the CPU. These conditions are:

- A rising edge on the EMIF_nWAIT signal (wait rise interrupt)
- An asynchronous time out
- Usage of unsupported addressing mode (line trap interrupt)

The wait rise interrupt occurs when a rising edge is detected on EMIF_nWAIT signal. This interrupt generation is not affected by the WP_n bit in the asynchronous wait cycle configuration register (AWCC). The asynchronous time out interrupt condition occurs when the attached asynchronous device fails to deassert the EMIF_nWAIT pin within the number of cycles defined by the MAX_EXT_WAIT bit in AWCC (this happens only in extended wait mode). EMIF supports only linear incrementing and cache line wrap addressing modes. If an access request for an unsupported addressing mode is received, the EMIF will set the LT bit in the EMIF interrupt raw register (INTRAW) and treat the request as a linear incrementing request.

Only when the interrupt is enabled by setting the appropriate bit (WR_MASK_SET/AT_MASK_SET/LT_MASK_SET) in the EMIF interrupt mask set register (INTMSKSET) to 1, will the interrupt be sent to the CPU. Once enabled, the interrupt may be disabled by writing a 1 to the corresponding bit in the EMIF interrupt mask clear register (INTMSKCLR). The bit fields in both the INTMSKSET and INTMSKCLR may be used to indicate whether the interrupt is enabled. When the interrupt is enabled, the corresponding bit field in both the INTMSKSET and INTMSKCLR will have a value of 1; when the interrupt is disabled, the corresponding bit field will have a value of 0.

The EMIF interrupt raw register (INTRAW) and the EMIF interrupt mask register (INTMSK) indicate the status of each interrupt. The appropriate bit (WR/AT/LT) in INTRAW is set when the interrupt condition occurs, whether or not the interrupt has been enabled. However, the appropriate bit (WR_MASKED/AT_MASKED/LT_MASKED) in INTMSK is set only when the interrupt condition occurs and the interrupt is enabled. Writing a 1 to the bit in INTRAW clears the INTRAW bit as well as the corresponding bit in INTMSK. [Table 17-23](#) contains a brief summary of the interrupt status and control bit fields. See [Section 17.3](#) for complete details on the register fields.

Table 17-23. Interrupt Monitor and Control Bit Fields

| Register Name | Bit Name | Description |
|--|-------------|--|
| EMIF interrupt raw register (INTRAW) | WR | This bit is set when an rising edge on the EMIF_nWAIT signal occurs. Writing a 1 clears the WR bit as well as the WR_MASKED bit in INTMSK. |
| | AT | This bit is set when an asynchronous timeout occurs. Writing a 1 clears the AT bit as well as the AT_MASKED bit in INTMSK. |
| | LT | This bit is set when an unsupported addressing mode is used. Writing a 1 clears LT bit as well as the LT_MASKED bit in INTMSK. |
| EMIF interrupt mask register (INTMSK) | WR_MASKED | This bit is set only when a rising edge on the EMIF_nWAIT signal occurs and the interrupt has been enabled by writing a 1 to the WR_MASK_SET bit in INTMSKSET. |
| | AT_MASKED | This bit is set only when an asynchronous timeout occurs and the interrupt has been enabled by writing a 1 to the AT_MASK_SET bit in INTMSKSET. |
| | LT_MASKED | This bit is set only when line trap interrupt occurs and the interrupt has been enabled by writing a 1 to the LT_MASK_SET bit in INTMSKSET. |
| EMIF interrupt mask set register (INTMSKSET) | WR_MASK_SET | Writing a 1 to this bit enables the wait rise interrupt. |
| | AT_MASK_SET | Writing a 1 to this bit enables the asynchronous timeout interrupt. |
| | LT_MASK_SET | Writing a 1 to this bit enables the line trap interrupt. |
| EMIF interrupt mask clear register (INTMSKCLR) | WR_MASK_CLR | Writing a 1 to this bit disables the wait rise interrupt. |
| | AT_MASK_CLR | Writing a 1 to this bit disables the asynchronous timeout interrupt. |
| | LT_MASK_CLR | Writing a 1 to this bit disables the line trap interrupt. |

17.2.10 DMA Event Support

EMIF memory controller is a DMA slave peripheral and therefore does not generate DMA events. Data read and write requests may be made directly, by masters and the DMA.

17.2.11 EMIF Signal Multiplexing

For details on EMIF signal multiplexing, see the I/O Multiplexing Module chapter of the technical reference manual.

17.2.12 Memory Map

For information describing the device memory-map, see your device-specific datasheet.

17.2.13 Priority and Arbitration

[Section 17.2.2](#) describes the external prioritization and arbitration among requests from different sources within the microcontroller. The result of this external arbitration is that only one request is presented to the EMIF at a time. Once the EMIF completes a request, the external arbiter then provides the EMIF with the next pending request.

Internally, the EMIF undertakes memory device transactions according to a strict priority scheme. The highest priority events are:

- A device reset.
- A write to any of the three least significant bytes of the SDRAM configuration register (SDCR).

Either of these events will cause the EMIF to immediately commence its initialization sequence as described in [Section 17.2.5.4](#).

Once the EMIF has completed its initialization sequence, it performs memory transactions according to the following priority scheme (highest priority listed first):

1. If the EMIF's backlog refresh counter is at the Refresh Must urgency level, the EMIF performs multiple SDRAM auto refresh cycles until the Refresh Release urgency level is reached.
2. If an SDRAM or asynchronous read has been requested, the EMIF performs a read operation.
3. If the EMIF's backlog refresh counter is at the Refresh Need urgency level, the EMIF performs an SDRAM auto refresh cycle.
4. If an SDRAM or asynchronous write has been requested, the EMIF performs a write operation.
5. If the EMIF's backlog refresh counter is at the Refresh May or Refresh Release urgency level, the EMIF performs an SDRAM auto refresh cycle.
6. If the value of the SR bit in SDCR has been set to 1, the EMIF will enter the self-refresh state as described in [Section 17.2.5.7](#).

After taking one of the actions listed above, the EMIF then returns to the top of the priority list to determine its next action.

Because the EMIF does not issue auto-refresh cycles when in the self-refresh state, the above priority scheme does not apply when in this state. See [Section 17.2.5.7](#) for details on the operation of the EMIF when in the self-refresh state.

17.2.14 System Considerations

This section describes various system considerations to keep in mind when operating the EMIF.

17.2.14.1 Asynchronous Request Times

In a system that interfaces to both SDRAM and asynchronous memory, the asynchronous requests must not take longer than the smaller of the following two values:

- t_{RAS} (typically 120 μ s) - to avoid violating the maximum time allowed between issuing an ACTV and PRE command to the SDRAM.
- $t_{Refresh\ Rate} \times 11$ (typically 15.7 μ s \times 11 = 172.7 μ s) - to avoid refresh violations on the SDRAM.

The length of an asynchronous request is controlled by multiple factors, the primary factor being the number of access cycles required to complete the request. For example, an asynchronous request for 4 bytes will require four access cycles using an 8-bit data bus and only two access cycle using a 16-bit data bus. The maximum request size that the EMIF can be sent is 16 words, therefore the maximum number of access cycles per memory request is 64 when the EMIF is configured with an 8-bit data bus. The length of the individual access cycles that make up the asynchronous request is determined by the programmed setup, strobe, hold, and turnaround values, but can also be extended with the assertion of the EMIF_nWAIT input signal up to a programmed maximum limit. It is up to the user to make sure that an entire asynchronous request does not exceed the timing values listed above when also interfacing to an SDRAM device. This can be done by limiting the asynchronous timing parameters.

17.2.14.2 Interface to External Peripheral or FIFO Memory

If EMIF is used to interface to an external peripheral or FIFO logic (for example, UHPI), it is recommended to use the host CPU's Memory Protection Unit (MPU) to define this external memory range as a region that is either strongly-ordered or of device type.

17.2.14.3 Interface to External SDRAM

If EMIF is used to interface to an external SDRAM, it is recommended to burst as much as possible to normal memory to improve the interface bandwidth.

17.2.15 Power Management

Power dissipation from the EMIF memory controller may be managed by following methods:

- Self-refresh mode
- Power-down mode
- Gating input clocks to the module off

Gating input clocks off to the EMIF memory controller achieves higher power savings when compared to the power savings of self-refresh or power down mode. The input clock VCLK3 can be turned off through the use of the Global Clock Module (GCM). Before gating clocks off, the EMIF memory controller must place the SDR SDRAM memory in self-refresh mode. If the external memory requires a continuous clock, the VCLK3 clock domain must not be turned off because this may result in data corruption. See the following subsections for the proper procedures to follow when stopping the EMIF memory controller clocks.

17.2.15.1 Power Management Using Self-Refresh Mode

The EMIF can be placed into a self-refresh state in order to place the attached SDRAM devices into self-refresh mode, which consumes less power for most SDRAM devices. In this state, the attached SDRAM device uses an internal clock to perform its own auto refresh cycles. This maintains the validity of the data in the SDRAM without the need for any external commands. Refer to [Section 17.2.5.7](#) for more details on placing the EMIF into the self-refresh state.

17.2.15.2 Power Management Using Power Down Mode

In the power down mode, EMIF drives EMIF_CKE low to lower the power consumption. EMIF_CKE goes high when there is a need to send refresh (REFR) commands, after which EMIF_CKE is again driven low. EMIF_CKE remains low until any request arrives. Refer to [Section 17.2.5.8](#) for more details on placing EMIF in power down mode.

17.2.16 Emulation Considerations

EMIF memory controller remains fully functional during emulation halts in order to allow emulation access to external memory.

17.3 EMIF Registers

The external memory interface (EMIF) is controlled by programming its internal memory-mapped registers (MMRs). [Table 17-24](#) lists the memory-mapped registers for the EMIF.

NOTE: All EMIF MMRs, except SDCR, support only word (32-bit) accesses. Performing a byte (8-bit) or halfword (16-bit) write to these registers results in undefined behavior. The SDCR is byte writable to allow the setting of the SR, PD, and PDWR bits without triggering the SDRAM initialization sequence.

The EMIF registers must always be accessed using 32-bit accesses (unless otherwise specified in this chapter). The base address of the EMIF memory-mapped registers is FCFF E800h.

Table 17-24. External Memory Interface (EMIF) Registers

| Offset | Acronym | Register Description | Section |
|--------|-----------|--|---------------------------------|
| 00h | MIDR | Module ID Register | Section 17.3.1 |
| 04h | AWCC | Asynchronous Wait Cycle Configuration Register | Section 17.3.2 |
| 08h | SDCR | SDRAM Configuration Register | Section 17.3.3 |
| 0Ch | SDRCR | SDRAM Refresh Control Register | Section 17.3.4 |
| 10h | CE2CFG | Asynchronous 1 Configuration Register | Section 17.3.5 |
| 14h | CE3CFG | Asynchronous 2 Configuration Register | Section 17.3.5 |
| 18h | CE4CFG | Asynchronous 3 Configuration Register | Section 17.3.5 |
| 1Ch | CE5CFG | Asynchronous 4 Configuration Register | Section 17.3.5 |
| 20h | SDTIMR | SDRAM Timing Register | Section 17.3.6 |
| 3Ch | SDSRETR | SDRAM Self Refresh Exit Timing Register | Section 17.3.7 |
| 40h | INTRAW | EMIF Interrupt Raw Register | Section 17.3.8 |
| 44h | INTMSK | EMIF Interrupt Mask Register | Section 17.3.9 |
| 48h | INTMSKSET | EMIF Interrupt Mask Set Register | Section 17.3.10 |
| 4Ch | INTMSKCLR | EMIF Interrupt Mask Clear Register | Section 17.3.11 |
| 68h | PMCR | Page Mode Control Register | Section 17.3.12 |

17.3.1 Module ID Register (MIDR)

This is a read-only register indicating the module ID of the EMIF. The MIDR is shown in [Figure 17-15](#) and described in [Table 17-25](#).

Figure 17-15. Module ID Register (MIDR) [offset = 00]

Table 17-25. Module ID Register (MIDR) Field Descriptions

| Bit | Field | Value | Description |
|------|-------|-------|---|
| 31-0 | REV | x | Module ID of EMIF. See the device-specific data manual. |

17.3.2 Asynchronous Wait Cycle Configuration Register (AWCC)

The asynchronous wait cycle configuration register (AWCC) is used to configure the parameters for extended wait cycles. Both the polarity of the EMIF_nWAIT pin(s) and the maximum allowable number of extended wait cycles can be configured. The AWCC is shown in Figure 17-16 and described in Table 17-26. Not all devices support both EMIF_nWAIT[1] and EMIF_nWAIT[0], see the device-specific data manual to determine support on each device.

NOTE: The EW bit in the asynchronous *n* configuration register (CE*n*CFG) must be set to allow for the insertion of extended wait cycles.

Figure 17-16. Asynchronous Wait Cycle Configuration Register (AWCCR) [offset = 04h]

| | | | | | | | | | | | | | |

Table 17-26. Asynchronous Wait Cycle Configuration Register (AWCCR) Field Descriptions

| Bit | Field | Value | Description |
|-------|--------------|------------------|--|
| 31-30 | Reserved | 3h | Reserved |
| 29 | WP1 | 0 1 | EMIF_nWAIT[1] polarity bit. This bit defines the polarity of the EMIF_nWAIT[1] pin. Insert wait cycles if EMIF_nWAIT[1] pin is low. Insert wait cycles if EMIF_nWAIT[1] pin is high. |
| 28 | WP0 | 0 1 | EMIF_nWAIT[0] polarity bit. This bit defines the polarity of the EMIF_nWAIT[0] pin. Insert wait cycles if EMIF_nWAIT[0] pin is low. Insert wait cycles if EMIF_nWAIT[0] pin is high. |
| 27-24 | Reserved | 0 | Reserved |
| 23-22 | CS5_WAIT | 0-3h | Chip Select 5 WAIT signal selection. This signal determines which EMIF_nWAIT[<i>n</i>] signal will be used for memory accesses to chip select 5 memory space. This device does not support chip select 5, so any value written to this field has no effect. |
| 21-20 | CS4_WAIT | 0 1h 2h-3h | Chip Select 4 WAIT signal selection. This signal determines which EMIF_nWAIT[<i>n</i>] signal will be used for memory accesses to chip select 4 memory space. EMIF_nWAIT[0] pin is used to control external wait states. EMIF_nWAIT[1] pin is used to control external wait states. Reserved |
| 19-18 | CS3_WAIT | 0 1h 2h-3h | Chip Select 3 WAIT signal selection. This signal determines which EMIF_nWAIT[<i>n</i>] signal will be used for memory accesses to chip select 3 memory space. EMIF_nWAIT[0] pin is used to control external wait states. EMIF_nWAIT[1] pin is used to control external wait states. Reserved |
| 17-16 | CS2_WAIT | 0 1h 2h-3h | Chip Select 2 WAIT signal selection. This signal determines which EMIF_nWAIT[<i>n</i>] signal will be used for memory accesses to chip select 2 memory space. EMIF_nWAIT[0] pin is used to control external wait states.. EMIF_nWAIT[1] pin is used to control external wait states. Reserved |
| 15-8 | Reserved | 0 | Reserved |
| 7-0 | MAX_EXT_WAIT | 0-FFh | Maximum extended wait cycles. The EMIF will wait for a maximum of (MAX_EXT_WAIT + 1) × 16 clock cycles before it stops inserting asynchronous wait cycles and proceeds to the hold period of the access. |

17.3.3 SDRAM Configuration Register (SDCR)

The SDRAM configuration register (SDCR) is used to configure various parameters of the SDRAM controller such as the number of internal banks, the internal page size, and the CAS latency to match those of the attached SDRAM device. In addition, this register is used to put the attached SDRAM device into Self-Refresh mode. The SDCR is shown in [Figure 17-17](#) and described in [Table 17-27](#).

NOTE: Writing to the lower three bytes of this register will cause the EMIF to start the SDRAM initialization sequence described in [Section 17.2.5.4](#).

Figure 17-17. SDRAM Configuration Register (SDCR) [offset = 08h]

| R-0 | R/W-2h | | | R-0 | R/W-0 | |

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

A. The NM bit must be set to 1 if the EMIF on your device only has 16 data bus pins.

Table 17-27. SDRAM Configuration Register (SDCR) Field Descriptions

| Bit | Field | Value | Description |
|-------|----------|--------|---|
| 31 | SR | 0 1 | Self-Refresh mode bit. This bit controls entering and exiting of the Self-Refresh mode described in Section 17.2.5.7 . The field should be written using a byte-write to the upper byte of SDCR to avoid triggering the SDRAM initialization sequence. Writing a 0 to this bit will cause connected SDRAM devices and the EMIF to exit the Self-Refresh mode. Writing a 1 to this bit will cause connected SDRAM devices and the EMIF to enter the Self-Refresh mode. |
| 30 | PD | 0 1 | Power Down bit. This bit controls entering and exiting of the power-down mode. The field should be written using a byte-write to the upper byte of SDCR to avoid triggering the SDRAM initialization sequence. If both SR and PD bits are set, the EMIF will go into Self Refresh. Writing a 0 to this bit will cause connected SDRAM devices and the EMIF to exit the power-down mode. Writing a 1 to this bit will cause connected SDRAM devices and the EMIF to enter the power-down mode. |
| 29 | PDWR | | Perform refreshes during power down. Writing a 1 to this bit will cause EMIF to exit power-down state and issue and AUTO REFRESH command every time Refresh May level is set. |
| 28-15 | Reserved | 0 | Reserved. The reserved bit location is always read as 0. If writing to this field, always write the default value of 0. |
| 14 | NM | 0 1 | Narrow mode bit. This bit defines whether a 16- or 32-bit-wide SDRAM is connected to the EMIF. This bit field must always be set to 1. Writing to this field triggers the SDRAM initialization sequence. 0 32-bit SDRAM data bus is used. 1 16-bit SDRAM data bus is used. |
| 13-12 | Reserved | 0 | Reserved. The reserved bit location is always read as 0. If writing to this field, always write the default value of 0. |

Table 17-27. SDRAM Configuration Register (SDCR) Field Descriptions (continued)

| Bit | Field | Value | Description |
|------|-------------|---|--|
| 11-9 | CL | 0-1h Reserved 2h CAS latency = 2 EMIF_CLK cycles 3h CAS latency = 3 EMIF_CLK cycles 4h-7h Reserved | CAS Latency. This field defines the CAS latency to be used when accessing connected SDRAM devices. A 1 must be simultaneously written to the BIT11_9LOCK bit field of this register in order to write to the CL bit field. Writing to this field triggers the SDRAM initialization sequence. |
| 8 | BIT11_9LOCK | 0 CL cannot be written. 1 CL can be written. | Bits 11 to 9 lock. CL can only be written if BIT11_9LOCK is simultaneously written with a 1. BIT11_9LOCK is always read as 0. Writing to this field triggers the SDRAM initialization sequence. |
| 7 | Reserved | 0 | Reserved. The reserved bit location is always read as 0. If writing to this field, always write the default value of 0. |
| 6-4 | IBANK | 0 1 bank SDRAM devices. 1 2 bank SDRAM devices. 2 4 bank SDRAM devices. 3h-7h Reserved. | Internal SDRAM Bank size. This field defines number of banks inside the connected SDRAM devices. Writing to this field triggers the SDRAM initialization sequence. |
| 3 | Reserved | 0 | Reserved. The reserved bit location is always read as 0. If writing to this field, always write the default value of 0. |
| 2-0 | PAGESIZE | 0 8 column address bits (256 elements per row) 1h 9 column address bits (512 elements per row) 2h 10 column address bits (1024 elements per row) 3h 11 column address bits (2048 elements per row) 4h-7h Reserved | Page Size. This field defines the internal page size of connected SDRAM devices. Writing to this field triggers the SDRAM initialization sequence. |

17.3.4 SDRAM Refresh Control Register (SDRCR)

The SDRAM refresh control register (SDRCR) is used to configure the rate at which connected SDRAM devices will be automatically refreshed by the EMIF. Refer to [Section 17.2.5.6](#) on the refresh controller for more details. The SDRCR is shown in [Figure 17-18](#) and described in [Table 17-28](#).

Figure 17-18. SDRAM Refresh Control Register (SDRCR) [offset = 0Ch]

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 17-28. SDRAM Refresh Control Register (SDRCR) Field Descriptions

| Bit | Field | Value | Description |
|-------|----------|---------|--|
| 31-16 | Reserved | 0 | Reserved. The reserved bit location is always read as 0. If writing to this field, always write the default value of 0. |
| 12-0 | RR | 0-1FFFh | Refresh Rate. This field is used to define the SDRAM refresh period in terms of EMIF_CLK cycles. Writing a value < 0x0020 to this field will cause it to be loaded with (2 × T_RFC) + 1 value from the SDRAM timing register (SDTIMR). |

17.3.5 Asynchronous *n* Configuration Registers (CE2CFG-CE5CFG)

The asynchronous *n* configuration registers (CE2CFG, CE3CFG, CE4CFG, and CE5CFG) are used to configure the shaping of the address and control signals during an access to asynchronous memory connected to CS2, CS3, CS4, and CS5, respectively. CS5 is not available on this device. It is also used to program the width of asynchronous interface and to select from various modes of operation. This register can be written prior to any transfer, and any asynchronous transfer following the write will use the new configuration. The CE n CFG is shown in [Figure 17-19](#) and described in [Table 17-29](#).

Figure 17-19. Asynchronous *n* Configuration Register (CE n CFG) [offset = 10h - 1Ch]

| | | | | | |
|-------------------------|-------------------------|---------|--------|-------------------------|-------|

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

A. The EW bit must be cleared to 0 when operating in NAND Flash mode.

B. This bit field must be cleared to 0 if the EMIF on your device does not have an EMIF_nWAIT pin.

Table 17-29. Asynchronous *n* Configuration Register (CE n CFG) Field Descriptions

| Bit | Field | Value | Description |
|-------|----------|------------------|--|
| 31 | SS | 0 1 | Select Strobe bit. This bit defines whether the asynchronous interface operates in Normal Mode or Select Strobe Mode. See Section 17.2.6 for details on the two modes of operation. Normal Mode enabled. Select Strobe Mode enabled. |
| 30 | EW | 0 1 | Extend Wait bit. This bit defines whether extended wait cycles will be enabled. See Section 17.2.6.6 on extended wait cycles for details. This bit field must be set to 0 if the EMIF on your device does not have an EMIF_nWAIT pin. Extended wait cycles disabled. Extended wait cycles enabled. |
| 29-26 | W_SETUP | 0-Fh | Write setup width in EMIF_CLK cycles, minus one cycle. See Section 17.2.6.3 for details. |
| 25-20 | W_STROBE | 0-3Fh | Write strobe width in EMIF_CLK cycles, minus one cycle. See Section 17.2.6.3 for details. |
| 19-17 | W_HOLD | 0-7h | Write hold width in EMIF_CLK cycles, minus one cycle. See Section 17.2.6.3 for details. |
| 16-13 | R_SETUP | 0-Fh | Read setup width in EMIF_CLK cycles, minus one cycle. See Section 17.2.6.3 for details. |
| 12-7 | R_STROBE | 0-3Fh | Read strobe width in EMIF_CLK cycles, minus one cycle. See Section 17.2.6.3 for details. |
| 6-4 | R_HOLD | 0-7h | Read hold width in EMIF_CLK cycles, minus one cycle. See Section 17.2.6.3 for details. |
| 3-2 | TA | 0-3h | Minimum Turn-Around time. This field defines the minimum number of EMIF_CLK cycles between reads and writes, minus one cycle. See Section 17.2.6.3 for details. |
| 1-0 | ASIZE | 0 1h 2h-3h | Asynchronous Data Bus Width. This field defines the width of the asynchronous device's data bus. 8-bit data bus 16-bit data bus Reserved |

17.3.6 SDRAM Timing Register (SDTIMR)

The SDRAM timing register (SDTIMR) is used to program many of the SDRAM timing parameters. Consult the SDRAM datasheet for information on the appropriate values to program into each field. The SDTIMR is shown in [Figure 17-20](#) and described in [Table 17-30](#).

Figure 17-20. SDRAM Timing Register (SDTIMR) [offset = 20h]

| | | | | | | | | | |

Table 17-30. SDRAM Timing Register (SDTIMR) Field Descriptions

| Bit | Field | Value | Description |
|-------|----------|-------|---|
| 31-27 | T_RFC | 0-1Fh | Specifies the Trfc value of the SDRAM. This defines the minimum number of EMIF_CLK cycles from Refresh (REFR) to Refresh (REFR), minus 1: $T_RFC = (Trfc/t_{EMIF_CLK}) - 1$ |
| 26-24 | T_RP | 0-7h | Specifies the Trp value of the SDRAM. This defines the minimum number of EMIF_CLK cycles from Precharge (PRE) to Activate (ACTV) or Refresh (REFR) command, minus 1: $T_RP = (Trp/t_{EMIF_CLK}) - 1$ |
| 23 | Reserved | 0 | Reserved. The reserved bit location is always read as 0. If writing to this field, always write the default value of 0. |
| 22-20 | T_RCD | 0-7h | Specifies the Trcd value of the SDRAM. This defines the minimum number of EMIF_CLK cycles from Active (ACTV) to Read (READ) or Write (WRT), minus 1: $T_RCD = (Trcd/t_{EMIF_CLK}) - 1$ |
| 19 | Reserved | 0 | Reserved. The reserved bit location is always read as 0. If writing to this field, always write the default value of 0. |
| 18-16 | T_WR | 0-7h | Specifies the Twr value of the SDRAM. This defines the minimum number of EMIF_CLK cycles from last Write (WRT) to Precharge (PRE), minus 1: $T_WR = (Twr/t_{EMIF_CLK}) - 1$ |
| 15-12 | T_RAS | 0-Fh | Specifies the Tras value of the SDRAM. This defines the minimum number of EMIF_CLK clock cycles from Activate (ACTV) to Precharge (PRE), minus 1: $T_RAS = (Tras/t_{EMIF_CLK}) - 1$ |
| 11-8 | T_RC | 0-Fh | Specifies the Trc value of the SDRAM. This defines the minimum number of EMIF_CLK clock cycles from Activate (ACTV) to Activate (ACTV), minus 1: $T_RC = (Trc/t_{EMIF_CLK}) - 1$ |
| 7 | Reserved | 0 | Reserved. The reserved bit location is always read as 0. If writing to this field, always write the default value of 0. |
| 6-4 | T_RRD | 0-7h | Specifies the Trrd value of the SDRAM. This defines the minimum number of EMIF_CLK clock cycles from Activate (ACTV) to Activate (ACTV) for a different bank, minus 1: $T_RRD = (Trrd/t_{EMIF_CLK}) - 1$ |
| 3-0 | Reserved | 0 | Reserved. The reserved bit location is always read as 0. If writing to this field, always write the default value of 0. |

17.3.7 SDRAM Self Refresh Exit Timing Register (SDSRETR)

The SDRAM self refresh exit timing register (SDSRETR) is used to program the amount of time between when the SDRAM exits Self-Refresh mode and when the EMIF issues another command. The SDSRETR is shown in [Figure 17-21](#) and described in [Table 17-31](#).

Figure 17-21. SDRAM Self Refresh Exit Timing Register (SDSRETR) [offset = 3Ch]

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 17-31. SDRAM Self Refresh Exit Timing Register (SDSRETR) Field Descriptions

| Bit | Field | Value | Description |
|------|----------|-------|--|
| 31-5 | Reserved | 0 | Reserved. The reserved bit location is always read as 0. |
| 4-0 | T_XS | 0-1Fh | This field specifies the minimum number of ECLKOUT cycles from Self-Refresh exit to any command, minus one. $T_XS = T_{xsr} / t_{EMIF_CLK} - 1$ |

17.3.8 EMIF Interrupt Raw Register (INTRAW)

The EMIF interrupt raw register (INTRAW) is used to monitor and clear the EMIF's hardware-generated Asynchronous Timeout Interrupt. The AT bit in this register will be set when an Asynchronous Timeout occurs regardless of the status of the EMIF interrupt mask set register (INTMSKSET) and EMIF interrupt mask clear register (INTMSKCLR). Writing a 1 to this bit will clear it. The EMIF on some devices does not have the EMIF_nWAIT pin; therefore, these registers and fields are reserved on those devices. The INTRAW is shown in Figure 17-22 and described in Table 17-32.

Figure 17-22. EMIF Interrupt Raw Register (INTRAW) [offset = 40h]

Table 17-32. EMIF Interrupt Raw Register (INTRAW) Field Descriptions

| Bit | Field | Value | Description |
|------|----------|-------|---|
| 31-3 | Reserved | 0 | Reserved. The reserved bit location is always read as 0. If writing to this field, always write the default value of 0. |
| 2 | WR | 0 | Wait Rise. This bit is set to 1 by hardware to indicate that a rising edge on the EMIF_nWAIT pin has occurred. |
| | | 0 | Indicates that a rising edge has not occurred on the EMIF_nWAIT pin. Writing a 0 has no effect. |
| | | 1 | Indicates that a rising edge has occurred on the EMIF_nWAIT pin. Writing a 1 will clear this bit and the WR_MASKED bit in the EMIF interrupt masked register (INTMSK). |
| 1 | LT | 0 | Line Trap. Set to 1 by hardware to indicate illegal memory access type or invalid cache line size. |
| | | 0 | Writing a 0 has no effect. |
| | | 1 | Indicates that a line trap has occurred. Writing a 1 will clear this bit as well as the LT_MASKED bit in the EMIF interrupt masked register (INTMSK). |
| 0 | AT | 0 | Asynchronous Timeout. This bit is set to 1 by hardware to indicate that during an extended asynchronous memory access cycle, the EMIF_nWAIT pin did not go inactive within the number of cycles defined by the MAX_EXT_WAIT field in the asynchronous wait cycle configuration register (AWCC). |
| | | 0 | Indicates that an Asynchronous Timeout has not occurred. Writing a 0 has no effect. |
| | | 1 | Indicates that an Asynchronous Timeout has occurred. Writing a 1 will clear this bit as well as the AT_MASKED bit in the EMIF interrupt masked register (INTMSK). |

17.3.9 EMIF Interrupt Masked Register (INTMSK)

Like the EMIF interrupt raw register (INTRAW), the EMIF interrupt masked register (INTMSK) is used to monitor and clear the status of the EMIF's hardware-generated Asynchronous Timeout Interrupt. The main difference between the two registers is that when the AT_MASKED bit in this register is set, an active-high pulse will be sent to the CPU interrupt controller. Also, the AT_MASKED bit field in INTMSK is only set to 1 if the associated interrupt has been enabled in the EMIF interrupt mask set register (INTMSKSET). The EMIF on some devices does not have the EMIF_nWAIT pin, therefore, these registers and fields are reserved on those devices. The INTMSK is shown in [Figure 17-23](#) and described in [Table 17-33](#).

Figure 17-23. EMIF Interrupt Mask Register (INTMSK) [offset = 44h]

Table 17-33. EMIF Interrupt Mask Register (INTMSK) Field Descriptions

| Bit | Field | Value | Description |
|------|-----------|-------|---|
| 31-3 | Reserved | 0 | Reserved. The reserved bit location is always read as 0. If writing to this field, always write the default value of 0. |
| 2 | WR_MASKED | 0 | Wait Rise Masked. This bit is set to 1 by hardware to indicate a rising edge has occurred on the EMIF_nWAIT pin, provided that the WR_MASK_SET bit is set to 1 in the EMIF interrupt mask set register (INTMSKSET). |
| | | 1 | Indicates that a wait rise interrupt has not been generated. Writing a 0 has no effect. |
| | | 1 | Indicates that a wait rise interrupt has been generated. Writing a 1 will clear this bit and the WR bit in the EMIF interrupt raw register (INTRAW). |
| 1 | LT_MASKED | 0 | Masked Line Trap. Set to 1 by hardware to indicate illegal memory access type or invalid cache line size, only if the LT_MASK_SET bit in the EMIF interrupt mask set register (INTMSKSET) is set to 1. |
| | | 1 | Writing a 0 has no effect. |
| | | 1 | Writing a 1 will clear this bit as well as the LT bit in the EMIF interrupt raw register (INTRAW). |
| 0 | AT_MASKED | 0 | Asynchronous Timeout Masked. This bit is set to 1 by hardware to indicate that during an extended asynchronous memory access cycle, the EMIF_nWAIT pin did not go inactive within the number of cycles defined by the MAX_EXT_WAIT field in the asynchronous wait cycle configuration register (AWCC), provided that the AT_MASK_SET bit is set to 1 in the EMIF interrupt mask set register (INTMSKSET). |
| | | 1 | Indicates that an Asynchronous Timeout Interrupt has not been generated. Writing a 0 has no effect. |
| | | 1 | Indicates that an Asynchronous Timeout Interrupt has been generated. Writing a 1 will clear this bit as well as the AT bit in the EMIF interrupt raw register (INTRAW). |

17.3.10 EMIF Interrupt Mask Set Register (INTMSKSET)

The EMIF interrupt mask set register (INTMSKSET) is used to enable the Asynchronous Timeout Interrupt. If read as 1, the AT_MASKED bit in the EMIF interrupt masked register (INTMSK) will be set and an interrupt will be generated when an Asynchronous Timeout occurs. If read as 0, the AT_MASKED bit will always read 0 and no interrupt will be generated when an Asynchronous Timeout occurs. Writing a 1 to the AT_MASK_SET bit enables the Asynchronous Timeout Interrupt. The EMIF on some devices does not have the EMIF_nWAIT pin; therefore, these registers and fields are reserved on those devices. The INTMSKSET is shown in [Figure 17-24](#) and described in [Table 17-34](#).

Figure 17-24. EMIF Interrupt Mask Set Register (INTMSKSET) [offset = 48h]

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 17-34. EMIF Interrupt Mask Set Register (INTMSKSET) Field Descriptions

| Bit | Field | Value | Description |
|------|-------------|-------|--|
| 31-3 | Reserved | 0 | Reserved. The reserved bit location is always read as 0. If writing to this field, always write the default value of 0. |
| 2 | WR_MASK_SET | 0 | Wait Rise Mask Set. This bit determines whether or not the wait rise Interrupt is enabled. Writing a 1 to this bit sets this bit, sets the WR_MASK_CLR bit in the EMIF interrupt mask clear register (INTMSKCLR), and enables the wait rise interrupt. To clear this bit, a 1 must be written to the WR_MASK_CLR bit in INTMSKCLR. |
| | | 1 | Indicates that the wait rise interrupt is disabled. Writing a 0 has no effect. |
| | | 1 | Indicates that the wait rise interrupt is enabled. Writing a 1 sets this bit and the WR_MASK_CLR bit in the EMIF interrupt mask clear register (INTMSKCLR). |
| 1 | LT_MASK_SET | 0 | Mask set for LT_MASKED bit in the EMIF interrupt mask register (INTMSK). |
| | | 1 | Indicates that the line trap interrupt is disabled. Writing a 0 has no effect. |
| | | 1 | Indicates that the line trap interrupt is enabled. Writing a 1 sets this bit and the LT_MASK_CLR bit in the EMIF interrupt mask clear register (INTMSKCLR). |
| 0 | AT_MASK_SET | 0 | Asynchronous Timeout Mask Set. This bit determines whether or not the Asynchronous Timeout Interrupt is enabled. Writing a 1 to this bit sets this bit, sets the AT_MASK_CLR bit in the EMIF interrupt mask clear register (INTMSKCLR), and enables the Asynchronous Timeout Interrupt. To clear this bit, a 1 must be written to the AT_MASK_CLR bit of the EMIF interrupt mask clear register (INTMSKCLR). |
| | | 1 | Indicates that the Asynchronous Timeout Interrupt is disabled. Writing a 0 has no effect. |
| | | 1 | Indicates that the Asynchronous Timeout Interrupt is enabled. Writing a 1 sets this bit and the AT_MASK_CLR bit in the EMIF interrupt mask clear register (INTMSKCLR). |

17.3.11 EMIF Interrupt Mask Clear Register (INTMSKCLR)

The EMIF interrupt mask clear register (INTMSKCLR) is used to disable the Asynchronous Timeout Interrupt. If read as 1, the AT_MASKED bit in the EMIF interrupt masked register (INTMSK) will be set and an interrupt will be generated when an Asynchronous Timeout occurs. If read as 0, the AT_MASKED bit will always read 0 and no interrupt will be generated when an Asynchronous Timeout occurs. Writing a 1 to the AT_MASK_CLR bit disables the Asynchronous Timeout Interrupt. The EMIF on some devices does not have the EMIF_nWAIT pin, therefore, these registers and fields are reserved on those devices. The INTMSKCLR is shown in [Figure 17-25](#) and described in [Table 17-35](#).

Figure 17-25. EMIF Interrupt Mask Clear Register (INTMSKCLR) [offset = 4Ch]

| | | | | | | | | | | | | | | | | | | | | |

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 17-35. EMIF Interrupt Mask Clear Register (INTMSKCLR) Field Descriptions

| Bit | Field | Value | Description |
|------|-------------|--------|--|
| 31-3 | Reserved | 0 | Reserved. The reserved bit location is always read as 0. If writing to this field, always write the default value of 0. |
| 2 | WR_MASK_CLR | 0 1 | Wait Rise Mask Clear. This bit determines whether or not the wait rise interrupt is enabled. Writing a 1 to this bit clears this bit, clears the WR_MASK_SET bit in the EMIF interrupt mask set register (INTMSKSET), and disables the wait rise interrupt. To set this bit, a 1 must be written to the WR_MASK_SET bit in INTMSKSET. 0 Indicates that the wait rise interrupt is disabled. Writing a 0 has no effect. 1 Indicates that the wait rise interrupt is enabled. Writing a 1 clears this bit and the WR_MASK_SET bit in the EMIF interrupt mask set register (INTMSKSET). |
| 1 | LT_MASK_CLR | 0 1 | Line trap Mask Clear. This bit determines whether or not the line trap interrupt is enabled. Writing a 1 to this bit clears this bit, clears the LT_MASK_SET bit in the EMIF interrupt mask set register (INTMSKSET), and disables the line trap interrupt. To set this bit, a 1 must be written to the LT_MASK_SET bit in INTMSKSET. 0 Indicates that the line trap interrupt is disabled. Writing a 0 has no effect. 1 Indicates that the line trap interrupt is enabled. Writing a 1 clears this bit and the LT_MASK_SET bit in the EMIF interrupt mask set register (INTMSKSET). |
| 0 | AT_MASK_CLR | 0 1 | Asynchronous Timeout Mask Clear. This bit determines whether or not the Asynchronous Timeout Interrupt is enabled. Writing a 1 to this bit clears this bit, clears the AT_MASK_SET bit in the EMIF interrupt mask set register (INTMSKSET), and disables the Asynchronous Timeout Interrupt. To set this bit, a 1 must be written to the AT_MASK_SET bit of the EMIF interrupt mask set register (INTMSKSET). 0 Indicates that the Asynchronous Timeout Interrupt is disabled. Writing a 0 has no effect. 1 Indicates that the Asynchronous Timeout Interrupt is enabled. Writing a 1 clears this bit and the AT_MASK_SET bit in the EMIF interrupt mask set register (INTMSKSET). |

17.3.12 Page Mode Control Register (PMCR)

The page mode control register (PMCR) is shown in [Figure 17-26](#) and described in [Table 17-36](#). This register is configured when using NOR Flash page mode.

Figure 17-26. Page Mode Control Register (PMCR) [offset = 68h]

| | | 0 | Page mode disabled for this chip select |
| | | 1 | Page mode enabled for this chip select |

17.4 Example Configuration

This section presents an example of interfacing the EMIF to both an SDR SDRAM device and an asynchronous flash device.

17.4.1 Hardware Interface

Figure 17-27 shows the hardware interface between the EMIF, a Samsung K4S641632H-TC(L)70 64Mb SDRAM device, and two SHARP LH28F800BJE-PTTL90 8Mb Flash memory. The connection between the EMIF and the SDRAM is straightforward, but the connection between the EMIF and the flash deserves a detailed look.

The address inputs for the flash are provided by three sources. The A[18:0] address inputs are provided by a combination of the EMIF_A and EMIF_BA pins according to Section 17.2.6.1. RD/nBY signal from one flash is connected to EMIF_nWAIT pin of EMIF.

Finally, this example configuration connects the EMIF_nWE pin to the nWE input of the flash and operates the EMIF in Select Strobe Mode.

17.4.2 Software Configuration

The following sections describe how to configure the EMIF registers and bit fields to interface the EMIF with the Samsung K4S641632H-TC(L)70 SDRAM and the SHARP LH28F800BJE-PTTL90 8Mb Flash memory.

17.4.2.1 Configuring the SDRAM Interface

This section describes how to configure the EMIF to interface with the Samsung K4S641632H-TC(L)70 SDRAM with a clock frequency of $f_{\text{EMIF_CLK}} = 100 \text{ MHz}$. Procedure A described in Section 17.2.5.5 is followed which assumes that the SDRAM power-up timing constraint were met during the SDRAM Auto-Initialization sequence after Reset.

17.4.2.1.1 PLL Programming for the EMIF to K4S641632H-TC(L)70 Interface

The device global clock module (GCM) should first be programmed to select the desired EMIF_CLK frequency. Before doing this, the SDRAM should be placed in Self-Refresh Mode by setting the SR bit in the SDRAM configuration register (SDCR). The SR bit should be set using a byte-write to the upper byte of the SDCR to avoid triggering the SDRAM Initialization Sequence. The EMIF_CLK frequency can now be configured to the desired value by selecting the appropriate clock source for the VCLK3 domain. Once the VCLK3 domain frequency has been configured, remove the SDRAM from Self-Refresh by clearing the SR bit in SDCR, again with a byte-write.

Table 17-37. SR Field Value For the EMIF to K4S641632H-TC(L)70 Interface

| Field | Value | Purpose |
|-------|----------|---|
| SR | 1 then 0 | To place the EMIF into the self refresh state |

17.4.2.1.2 SDRAM Timing Register (SDTIMR) Settings for the EMIF to K4S641632H-TC(L)70 Interface

The fields of the SDRAM timing register (SDTIMR) should be programmed first as described in [Table 17-38](#) to satisfy the required timing parameters for the K4S641632H-TC(L)70. Based on these calculations, a value of 6111 4610h should be written to SDTIMR. [Figure 17-28](#) shows a graphical description of how SDTIMR should be programmed.

Table 17-38. SDTIMR Field Calculations for the EMIF to K4S641632H-TC(L)70 Interface

| Field Name | Formula | Value from K4S641632H-TC(L)70 Datasheet | Value Calculated for Field |
|------------|--|---|----------------------------|
| T_RFC | $T_RFC \geq (t_{RFC} \times f_{EMIF_CLK}) - 1$ | $t_{RC} = 68 \text{ ns (min)}^{(1)}$ | 6 |
| T_RP | $T_RP \geq (t_{RP} \times f_{EMIF_CLK}) - 1$ | $t_{RP} = 20 \text{ ns (min)}$ | 1 |
| T_RCD | $T_RCD \geq (t_{RCD} \times f_{EMIF_CLK}) - 1$ | $t_{RCD} = 20 \text{ ns (min)}$ | 1 |
| T_WR | $T_WR \geq (t_{WR} \times f_{EMIF_CLK}) - 1$ | $t_{RDL} = 2 \text{ CLK} = 20 \text{ ns (min)}^{(2)}$ | 1 |
| T_RAS | $T_RAS \geq (t_{RAS} \times f_{EMIF_CLK}) - 1$ | $t_{RAS} = 49 \text{ ns (min)}$ | 4 |
| T_RC | $T_RC \geq (t_{RC} \times f_{EMIF_CLK}) - 1$ | $t_{RC} = 68 \text{ ns (min)}$ | 6 |
| T_RRD | $T_RRD \geq (t_{RRD} \times f_{EMIF_CLK}) - 1$ | $t_{RRD} = 14 \text{ ns (min)}$ | 1 |

⁽¹⁾ The Samsung datasheet does not specify a t_{RFC} value. Instead, Samsung specifies t_{RC} as the minimum auto refresh period.

⁽²⁾ The Samsung datasheet does not specify a t_{WR} value. Instead, Samsung specifies t_{RDL} as last data in to row precharge minimum delay.

Figure 17-28. SDRAM Timing Register (SDTIMR)

| | | | | | | | | | |
|--------|------|------|-------|----------|------|----|-----|----|----|
| 31 | 27 | 26 | 24 | 23 | 22 | 20 | 19 | 18 | 16 |

17.4.2.1.3 SDRAM Self Refresh Exit Timing Register (SDSRETR) Settings for the EMIF to K4S641632H-TC(L)70 Interface

The SDRAM self refresh exit timing register (SDSRETR) should be programmed second to satisfy the t_{XSR} timing requirement from the K4S641632H-TC(L)70 datasheet. Table 17-39 shows the calculation of the proper value to program into the T_XS field of this register. Based on this calculation, a value of 6h should be written to SDSRETR. Figure 17-29 shows how SDSRETR should be programmed.

Table 17-39. RR Calculation for the EMIF to K4S641632H-TC(L)70 Interface

| Field Name | Formula | Value from K4S641632H-TC(L)70 Datasheet | Value Calculated for Field |
|------------|---|---|----------------------------|
| T_XS | $T_XS \geq (t_{XSR} \times f_{EMIF_CLK}) - 1$ | $t_{RC} = 68 \text{ ns (min)}^{(1)}$ | 6 |

⁽¹⁾ The Samsung datasheet does not specify a t_{XSR} value. Instead, Samsung specifies t_{RC} as the minimum required time after CKE going high to complete self refresh exit.

Figure 17-29. SDRAM Self Refresh Exit Timing Register (SDSRETR)

| | | | | | | | | | | | | | | | | | |
|---------------------|--|--|--|--|--|--|--|--|--|--|--------|---|--|--|--|---|----|
| 31 | | | | | | | | | | | | | | | | | 16 |
| 0000 0000 0000 0000 | | | | | | | | | | | | | | | | | |

17.4.2.1.4 SDRAM Refresh Control Register (SDRCR) Settings for the EMIF to K4S641632H-TC(L)70 Interface

The SDRAM refresh control register (SDRCR) should next be programmed to satisfy the required refresh rate of the K4S641632H-TC(L)70. Table 17-40 shows the calculation of the proper value to program into the RR field of this register. Based on this calculation, a value of 61Ah should be written to SDRCR. Figure 17-30 shows how SDRCR should be programmed.

Table 17-40. RR Calculation for the EMIF to K4S641632H-TC(L)70 Interface

| Field Name | Formula | Values | Value Calculated for Field |
|------------|--|--|--|
| RR | $RR \leq f_{EMIF_CLK} \times t_{Refresh \text{ Period}} / n_{cycles}$ | From SDRAM datasheet: $t_{Refresh \text{ Period}} = 64 \text{ ms}$; $n_{cycles} = 4096 \text{ EMIF clock rate: } f_{EMIF_CLK} = 100 \text{ MHz}$ | $RR = 1562 \text{ cycles} = 61Ah \text{ cycles}$ |

Figure 17-30. SDRAM Refresh Control Register (SDRCR)

| | | | | | | | | | | | | | | | | | |

| Reserved | | | RR | | | | | | | | | | | | | | |

17.4.2.1.5 SDRAM Configuration Register (SDCR) Settings for the EMIF to K4S641632H-TC(L)70 Interface

Finally, the fields of the SDRAM configuration register (SDCR) should be programmed as described in [Table 17-37](#) to properly interface with the K4S641632H-TC(L)70 device. Based on these settings, a value of 4720h should be written to SDCR. [Figure 17-31](#) shows how SDCR should be programmed. The EMIF is now ready to perform read and write accesses to the SDRAM.

Table 17-41. SDCR Field Values For the EMIF to K4S641632H-TC(L)70 Interface

| Field | Value | Purpose |
|-------------|-------|---|
| SR | 0 | To avoid placing the EMIF into the self refresh state |
| NM | 1 | To configure the EMIF for a 16-bit data bus |
| CL | 011b | To select a CAS latency of 3 |
| BIT11_9LOCK | 1 | To allow the CL field to be written |
| IBANK | 010b | To select 4 internal SDRAM banks |
| PAGESIZE | 0 | To select a page size of 256 words |

17.4.2.2 Configuring the Flash Interface

This section describes how to configure the EMIF to interface with the two of SHARP LH28F800BJE-PTTL90 8Mb Flash memory with a clock frequency of $f_{\text{EMIF_CLK}} = 100 \text{ MHz}$. The example assumes that one flash is connected to EMIF_nCS2 and the other to EMIF_nCS3.

17.4.2.2.1 Asynchronous 1 Configuration Register (CE2CFG) Settings for the EMIF to LH28F800BJE-PTTL90 Interface

The asynchronous 1 configuration register (CE2CFG) and asynchronous 2 configuration register (CE3CFG) are the only registers that is necessary to program for this asynchronous interface (assuming that one Flash is connected to EMIF_nCS[2] and the other to EMIF_nCS[3]. The SS bit (in both registers) should be set to 1 to enable Select Strobe Mode and the ASIZE field (in both registers) should be set to 1 to select a 16-bit interface. The other fields in this register control the shaping of the EMIF signals, and the proper values can be determined by referring to the AC Characteristics in the Flash datasheet and the device datasheet. Based on the following calculations, a value of 8862 25BDh should be written to CE2CFG. Table 17-42 and Table 17-43 show the pertinent AC Characteristics for reads and writes to the Flash device, and Figure 17-32 and Figure 17-33 show the associated timing waveforms. Finally, Figure 17-34 shows programming the CE n CFG ($n = 2, 3$) with the calculated values.

Table 17-42. AC Characteristics for a Read Access

| AC Characteristic | Device | Definition | Min | Max | Unit |
|-------------------|--------|---|-----|-----|------|
| t_{SU} | EMIF | Setup time, read EMIF_D before EMIF_CLK high | 6.5 | | ns |
| t_{H} | EMIF | Data hold time, read EMIF_D after EMIF_CLK high | 1 | | ns |
| t_{D} | EMIF | Output delay time, EMIF_CLK high to output signal valid | | 7 | ns |
| t_{ELQV} | Flash | nCE to Output Delay | | 90 | ns |
| t_{EHQZ} | Flash | nCE High to Output in High Impedance | | 55 | ns |

Table 17-43. AC Characteristics for a Write Access

| AC Characteristic | Device | Definition | Min | Max | Unit |
|-------------------|--------|--|-----|-----|------|
| t_{AVAV} | Flash | Write Cycle Time | 90 | | ns |
| t_{ELEH} | Flash | nCE Pulse Width Low | 50 | | ns |
| t_{EHEL} | Flash | nCE Pulse Width High (not shown in Figure 17-33) | 30 | | ns |

Figure 17-32. LH28F800BJE-PTTL90 to EMIF Read Timing Waveforms

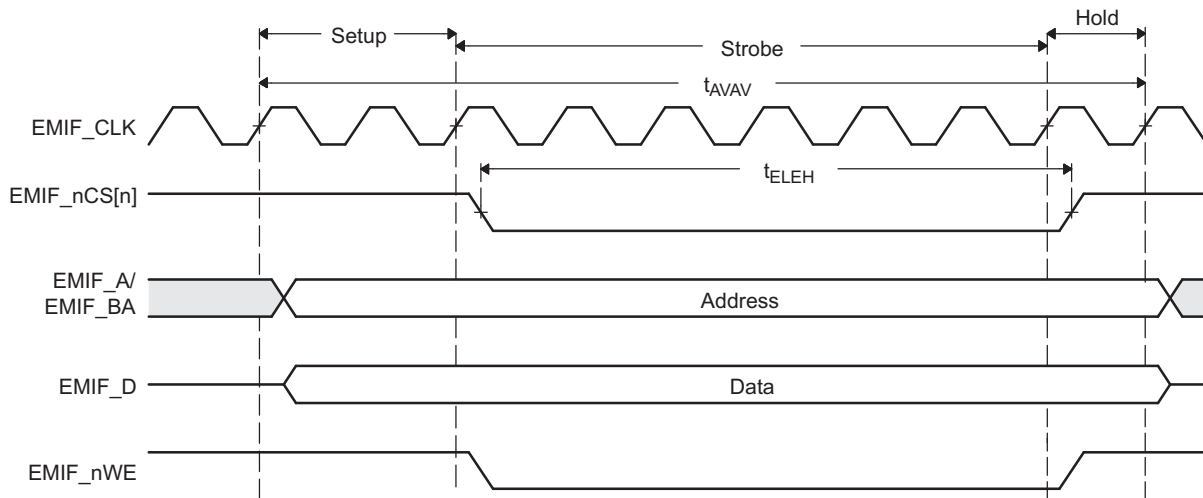

Figure 17-33. LH28F800BJE-PTTL90 to EMIF Write Timing Waveforms

The R_STROBE field should be set to meet the following equation:

$$R_STROBE \geq (t_D + t_{ELQV} + t_{SU}) \times f_{EMIF_CLK} - 1$$

$$R_STROBE \geq (7 \text{ ns} + 90 \text{ ns} + 6.5 \text{ ns}) \times 100 \text{ MHz} - 1$$

$$R_STROBE \geq 9.35$$

$$R_STROBE = 10$$

The R_HOLD field must be large enough to satisfy the EMIF Data hold time, t_H :

$$R_HOLD \geq t_H \times f_{EMIF_CLK} - 1$$

$$R_HOLD \geq 1 \text{ ns} \times 100 \text{ MHz} - 1$$

$$R_HOLD \geq -0.9$$

The R_HOLD field must also combine with the TA field to satisfy the Flash's nCE High to Output in High Impedance time, t_{EHQZ} :

$$R_HOLD + TA \geq (t_D + t_{EHQZ}) \times f_{EMIF_CLK} - 2$$

$$R_HOLD + TA \geq (7 \text{ ns} + 55 \text{ ns}) \times 100 \text{ MHz} - 2$$

$$R_HOLD + TA \geq 4.2$$

The largest value that can be programmed into the TA field is 3h, therefore the following values can be used:

$$R_HOLD = 2$$

$$TA = 3$$

For Writes, the W_STROBE field should be set to satisfy the Flash's nCE Pulse Width constraint, t_{ELEH} :

$$W_STROBE \geq t_{ELEH} \times f_{EMIF_CLK} - 1$$

$$W_STROBE \geq 50 \text{ ns} \times 100 \text{ MHz} - 1$$

$$W_STROBE \geq 4$$

The W_SETUP and W_HOLD fields should combine to satisfy the Flash's nCE Pulse Width High constraint, t_{EHEL} , when performing back-to-back writes:

$$W_SETUP + W_HOLD \geq t_{\text{EHEL}} \times f_{\text{EMIF_CLK}} - 2$$

$$W_SETUP + W_HOLD \geq 30 \text{ ns} \times 100 \text{ MHz} - 2$$

$$W_SETUP + W_HOLD \geq 1$$

In addition, the entire Write access length must satisfy the Flash's minimum Write Cycle Time, t_{AVAV} :

$$W_SETUP + W_STROBE + W_HOLD \geq t_{\text{AVAV}} \times f_{\text{EMIF_CLK}} - 3$$

$$W_SETUP + W_STROBE + W_HOLD \geq 90 \text{ ns} \times 100 \text{ MHz} - 3$$

$$W_SETUP + W_STROBE + W_HOLD \geq 6$$

Solving the above equations for the Write fields results in the following possible solution:

$$W_SETUP = 1$$

$$W_STROBE = 5$$

$$W_HOLD = 0$$

Adding a 10 ns (1 cycle) margin to each of the periods (excluding TA which is already at its maximum) in this example produces the following recommended values:

$$W_SETUP = 2h$$

$$W_STROBE = 6h$$

$$W_HOLD = 1h$$

$$R_SETUP = 1h$$

$$R_STROBE = 8h$$

$$R_HOLD = 3h$$

$$TA = 3h$$

Parameter Overlay Module (POM)

This chapter describes the parameter overlay module (POM).

| Topic | Page |
|-------------------------------------|-------------|
| 18.1 Introduction | 688 |
| 18.2 Module Operation | 689 |
| 18.3 Control Registers | 691 |

18.1 Introduction

In many applications it is important to be able to change certain parameters in the program without having to re-flash the device and immediately test these changes either in a hardware-in-the-loop simulation or in a real environment.

The POM provides a mechanism to redirect accesses to non-volatile memory into a volatile memory internal or external to the device. The data requested by the CPU will be fetched from the overlay memory instead of the main non-volatile memory.

18.1.1 Main Features

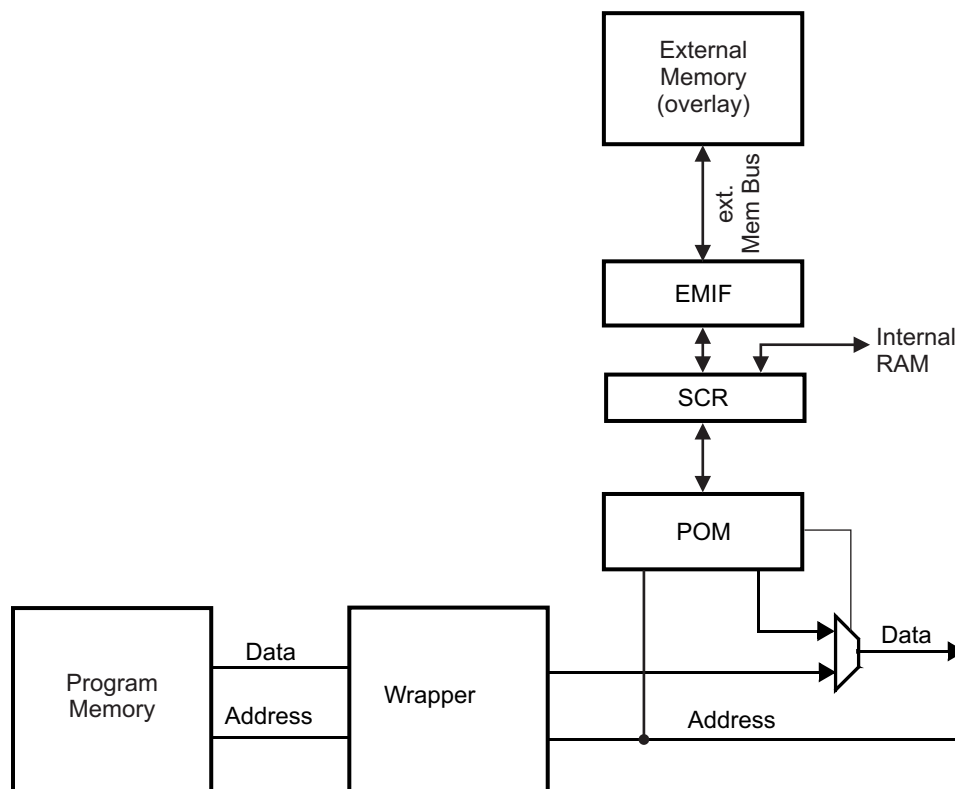

- Redirects program memory accesses to internal or external memory (overlay memory)
- Up to 8 MByte of external overlay memory
- Provides up to 32 programmable memory regions to replace non-volatile memory
 - Programmable region start address
 - Programmable region size (64 Bytes up to 256 kBytes in power of 2 steps)

18.1.2 Parameter Overlay Module (POM) Considerations

- The POM can map onto up to 8MB of the internal or external memory space. The starting address and the size of the memory overlay are configurable through the POM control registers. Care must be taken to ensure that the overlay is mapped on to available memory.
- ECC must be disabled by software through CP15 in case POM overlay is enabled; otherwise ECC errors will be generated.
- POM overlay must not be enabled when the flash and internal RAM memories are swapped through the MEM SWAP field of the Bus Matrix Module Control Register 1 (BMMCR1).
- When POM is used to overlay the flash on to internal or external RAM, there is a bus contention possibility when another master accesses the TCM flash. This results in a system hang.
 - The POM implements a timeout feature to detect this exact scenario. The timeout needs to be enabled whenever POM overlay is enabled.
 - The timeout can be enabled by writing Ah to the enable timeout (ETO) field of the POM global control register (POMGLBCTRL).
 - In case a read request by the POM cannot be completed within 32 HCLK cycles, the timeout (TO) flag is set in the POM status register (POMFLG). Also, an abort is generated to the CPU. This can be a prefetch abort for an instruction fetch or a data abort for a data fetch.
 - The prefetch-abort and data-abort handlers must be modified to check if the TO flag in the POM is set. If so, then the application can assume that the timeout is caused by a bus contention between the POM transaction and another master accessing the same memory region. The abort handlers need to clear the TO flag, so that any further aborts are not misinterpreted as having been caused due to a timeout from the POM.

18.1.3 Block Diagram

Figure 18-1. System Overlay Block Diagram

18.2 Module Operation

The POM has up to 32 programmable regions. Whenever the CPU requests data from the non-volatile memory which address falls into one of the programmed regions, the POM will request the data from the overlay memory. Wait states will be automatically inserted until the data is available from the overlay memory. This ensures that the overlay memory has the same (in the case that the latency from overlay memory is less than the program memory latency) or slower access time than the program memory.

The POM does not provide a feature to write into the overlay memory. The write has to be performed directly to the memory mapped address space of the overlay memory.

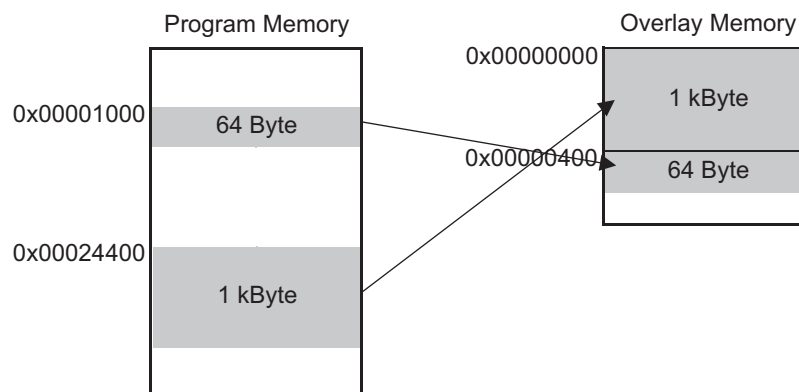

When the module is disabled, no redirection of access will be performed.

NOTE: The overlay feature is not available for any other bus masters other than the main CPU. Any attempt to access overlaid memory via the POM by any other bus master would result in a deadlock situation (system hang). Other bus masters need to access the target internal or external memory directly.

18.2.1 Decode Regions

There are 32 decode regions. Regions are defined by a start address and a region size. The start address is 23 bits wide to cover the maximum 8 MByte address space defined for program memory. The region size ranges from 64 Bytes to 256 kBytes with a step size of power of 2. If a region size of 0 is selected, the region is disabled. To support overlay memory that is not the same size as the program memory, an overlay start address that is 23-bits wide can be specified. The size of the overlay region is the same as the program memory region. The start address of both program memory and overlay memory region have to be a multiple of the programmed region size. When the address of the access falls into one of the programmed regions, the POM will start requesting the data from the overlay memory address, based on the overlay start address. If the address falls into multiple overlapping regions, the region with the lowest number has highest priority and only one read request from overlay memory will be initiated. This avoids that regions with the same program memory address, but different overlay memory addresses, request different data.

Figure 18-2. Region Definition Example

18.2.2 Bus Errors on Accesses via POM

In case a read by the POM cannot be completed within 32 HCLK cycles due to other transactions ongoing or due to other bus errors, a timeout mechanism is implemented. This timeout mechanism is disabled by default and must be enabled by writing Ah to the enable timeout (ETO) field of the POM global control register (POMGLBCTRL).

An abort is generated to the host CPU when this timeout occurs. The host CPU responds by either taking the prefetch abort or the data abort exceptions depending on the nature of the access that caused the timeout.

The abort handler can check if the TO flag is set in the POM module's flag register (POMFLG). If this flag is set, then the application can assume that the timeout is caused by the POM access not completing. This flag must be cleared so that any further aborts are not misinterpreted as having been caused by timeout on a POM access.

18.3 Control Registers

Table 18-1 lists the Parameter Overlay Module registers. The registers support only 32-bit writes. The offset is relative to the associated peripheral select. The base address for the control packets is FFA0 4000h.

Table 18-1. POM Registers

| Offset | Acronym | Register Description | Section |
|-----------------------|------------------|---|---------------------------------|
| 00h | POMGLBCTRL | POM Global Control Register | Section 18.3.1 |

18.3.1 POM Global Control Register (POMGLBCTRL)

This register contains a key to enable the POM module. Logic remains reset until this key is set.

Figure 18-3. POM Global Control Register (POMGLBCTRL) [address = FFA0 4000h]

| | | | | | |
|----------|----|---------|----|----------|----|

| | | | | ON/OFF | |
| | | | | R/WP-5h | |

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 18-2. POM Global Control Register (POMGLBCTRL) Field Descriptions

| Bit | Field | Value | Description |
|-------|----------|------------------------|--|
| 31-23 | OTADDR | 60h | Overlay target Address. These bits determine the upper address bits of the target overlay address. Writing a different value to this field will steer the POM access to a different location in the 4GB address space. The application must ensure that the overlay memory address points to a valid internal or external memory location. |
| 22-12 | Reserved | 0 | Reads return zeros, writes have no effect. |
| 11-8 | ETO | Ah All other values | Enable Timeout. Refer to Section 18.2.2 for more details on the timeout error. Timeout for bus transactions is enabled. Timeout for bus transactions is disabled. The timeout is disabled by default. |
| 7-4 | Reserved | 0 | Reads return zeros, writes have no effect. |
| 3-0 | ON/OFF | Ah All other values | Turn functionality of POM on or off. POM is functional. POM is held in reset. NOTE: The key should be written to 5h, to avoid single bit flips inadvertently turning on the module. |

18.3.2 POM Revision ID (POMREV)

This register contains the revision ID of the POM module.

Figure 18-4. POM Revision ID (POMREV) [address = FFA0 4004h]

| | | | | | | | | | | |
|--------|----|----------|----|--------|----|--------|---|-------|---|----|
| 31 | 30 | 29 | 28 | 27 | | | | | | 16 |

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 18-3. POM Revision ID (POMREV) Field Descriptions

| Bit | Field | Value | Description |
|-------|----------|-------|---|
| 31-30 | SCHEME | 1h | Used to distinguish between different ID schemes. |
| 29-28 | Reserved | 0 | Read returns 0. Writes have no effect. |
| 27-16 | FUNC | A03h | Indicates the SW compatible module family |
| 15-11 | RTL | 0 | RTL version number |
| 10-8 | MAJOR | 1h | Major revision number |
| 7-6 | CUSTOM | 0 | Indicates a device specific implementation |
| 5-0 | MINOR | 8h | Minor revision number |

18.3.3 POM Clock Gate Control Register (POMCLKCTRL)

This register is for TI internal use only.

Figure 18-5. POM Clock Gate Control Register [address = FFA0 4008h]

| | | | |
|----------|--|--|--------------|
| 31 | | | 16 |
| Reserved | | | |
| R-0 | | | |
| 15 | | | 0 |
| Reserved | | | CLK GATE OFF |
| R-0 | | | R/W-0 |

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 18-4. POM Clock Gate Control Register (POMCLKCTRL) Field Descriptions

| Bit | Field | Value | Description |
|------|--------------|-------|---|
| 31-1 | Reserved | 0 | Read returns 0. Writes have no effect. |
| 0 | CLK GATE OFF | 0 | Do not modify this bit. Leave it in its reset state. Modifying the bit while the POM module is switched on can result in unexpected behavior. |

18.3.4 POM Status Register (POMFLG)

This register provides POM status information.

Figure 18-6. POM Status Register [address = FFA0 400Ch]

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 18-5. POM Status Register (POMFLG) Field Descriptions

| Bit | Field | Value | Description |
|------|----------|-------|--|
| 31-1 | Reserved | 0 | Read returns 0. Writes have no effect. |
| 0 | TO | | Timeout. This flag signals a timeout condition on the last CPU read access through the POM. This flag is only updated when the POM module is enabled (ON/OFF = Ah). 0 No timeout occurred. Writing a 0 has no effect. 1 Timeout occurred. This flag can be cleared by writing a 1 to it. |

18.3.5 POM Program Region Start Address Register x (POMPROGSTARTx)

This register contains the start address of the region in program memory. x goes from 0 to 31, since up to 32 regions can be defined.

Figure 18-7. POM Program Region Start Register x (POMPROGSTARTx) [address = FFA0 4200h, FFA0 4210h, ..., FFA0 43F0h]

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 18-6. POM Program Region Start Address Register x (POMPROGSTARTx) Field Descriptions

| Bit | Field | Value | Description |
|-------|--------------|-------|--|
| 31-23 | Reserved | 0 | Read returns 0. Writes have no effect. |
| 22-0 | STARTADDRESS | | Defines the start address of the program memory region. The start address has to be a multiple of the region size. |

NOTE: If the region start address is programmed to a non-region size boundary, the region will begin at the next lower region size boundary.

18.3.6 POM Overlay Region Start Address Register x (POMOVLSTARTx)

This register contains the start address of the region in overlay memory. x goes from 0 to 31, since up to 32 regions can be defined.

Figure 18-8. POM Overlay Region Start Register x (POMOVLSTARTx) [address = FFA0 4204h, FFA0 4214h, ..., FFA0 43F4h]

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 18-7. POM Overlay Region Start Address Register x (POMOVLSTARTx) Field Descriptions

| Bit | Field | Value | Description |
|-------|--------------|-------|--|
| 31-23 | Reserved | 0 | Read returns 0. Writes have no effect. |
| 22-0 | STARTADDRESS | | Defines the start address of the overlay memory region. The start address has to be a multiple of the region size. |

NOTE: If the region start address is programmed to a non-region size boundary, the region will begin at the next lower region size boundary.

18.3.7 POM Region Size Register x (POMREGSIZEEx)

This register contains the region size for both program memory and overlay memory. x goes from 0 to 31, since up to 32 regions can be defined.

Figure 18-9. POM Region Size Register x (POMREGSIZEEx) [address = FFA0 4208h, FFA0 4218h, ..., FFA0 43F8h]

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 18-8. POM Region Size Register x (POMREGSIZEEx) Field Descriptions

| Bit | Field | Value | Description |
|------|----------|--|---|
| 31-4 | Reserved | 0 | Read returns 0. Writes have no effect. |
| 3-0 | SIZE | <div>0</div> <div>1h</div> <div>2h</div> <div>:</div> <div>Dh</div> <div>Eh-Fh</div> | Region size Region disabled 64 Bytes 128 Bytes : 256 kBytes Reserved |

NOTE: If the region is enabled by writing a non-zero value to the SIZE bitfield, it will take some number of VCLK cycles until the write takes effect. If during this time an access to the programmed region is taking place and the POM is already enabled in the POMGLBCTRL register, it either decodes the previous setting of the SIZE field or the access will be directed to the program memory when the region was disabled.

18.3.8 POM Integration Control Register (POMITCTRL)

This is a CoreSight register and is for debug purpose only. The integration functionality is not implemented. The register reads 00000000.

Figure 18-10. POM Integration Control Register (POMITCTRL) [address = FFA0 4F00h]

LEGEND: R = Read only; -n = value after reset

Table 18-9. POM Integration Control Register (POMITCTRL) Field Descriptions

| Bit | Field | Value | Description |
|------|----------|-------|--|
| 31-0 | Reserved | 0 | Read returns 0. Writes have no effect. |

18.3.9 POM Claim Set Register (POMCLAIMSET)

This is a CoreSight register and is for debug purpose only. This register allows different masters to claim the control for the POM module. There is no control functionality for POM register accesses implemented. The only functionality of these bits is to indicate that another master is controlling the module.

Figure 18-11. POM Claim Set Register (POMCLAIMSET) [address = FFA0 4FA0h]

| | | | | | | | | | | | | | |

| Bit | Field | Value | Description |
|------|----------|-------|--|
| 31-2 | Reserved | 0 | Read returns 0. Writes have no effect. |
| 1 | SET1 | 0 | The module is claimed Read: This claim tag bit is not implemented Write: no effect |
| | | 1 | Read: This claim tag is implemented Write: Set claim tag |
| 0 | SET0 | 0 | The module is claimed Read: This claim tag bit is not implemented Write: no effect |
| | | 1 | Read: This claim tag is implemented Write: Set claim tag |

18.3.10 POM Claim Clear Register (POMCLAIMCLR)

This is a CoreSight register and is for debug purpose only. This register allows different masters to claim the control for the POM module. There is no control functionality for POM register accesses implemented. The only functionality of these bits is to indicate that another master is controlling the module.

Figure 18-12. POM Claim Clear Register (POMCLAIMCLR) [address = FFA0 4FA4h]

| | | | | | | | | | | | | | | | | | |

Enhanced Pulse Width Modulator (ePWM) Module

The enhanced pulse width modulator (ePWM) peripheral is a key element in controlling many of the power electronic systems found in both commercial and industrial equipments. The features supported by the ePWM make it especially suitable for digital motor control.

| Topic | Page |
|---|------------|
| 19.1 Introduction | 708 |
| 19.2 ePWM Submodules..... | 712 |
| 19.3 Application Examples | 771 |
| 19.4 ePWM Module Control and Status Registers..... | 787 |

19.1 Introduction

An effective PWM peripheral must be able to generate complex pulse width waveforms with minimal CPU overhead or intervention. It needs to be highly programmable and very flexible while being easy to understand and use. The ePWM unit described here addresses these requirements by allocating all needed timing and control resources on a per PWM channel basis. Cross coupling or sharing of resources has been avoided; instead, the ePWM is built up from smaller single channel modules with separate resources that can operate together as required to form a system. This modular approach results in an orthogonal architecture and provides a more transparent view of the peripheral structure, helping users to understand its operation quickly.

In this document the letter x within a signal or module name is used to indicate a generic ePWM instance on a device. For example, output signals EPWMxA and EPWMxB refer to the output signals from the ePWMx instance. Thus, EPWM1A and EPWM1B belong to ePWM1 and likewise EPWM4A and EPWM4B belong to ePWM4.

19.1.1 Submodule Overview

The ePWM module represents one complete PWM channel composed of two PWM outputs: EPWMxA and EPWMxB. Multiple ePWM modules are instanced within a device as shown in [Figure 19-1](#). Each ePWM instance is identical and is indicated by a numerical value starting with 1. For example, ePWM1 is the first instance and ePWM3 is the third instance in the system and ePWMx indicates any instance.

The ePWM modules are chained together via a clock synchronization scheme that allows them to operate as a single system when required. Additionally, this synchronization scheme can be extended to the capture peripheral modules (eCAP). Modules can also operate stand-alone.

Each ePWM module supports the following features:

- Dedicated 16-bit time-base counter with period and frequency control
- Two PWM outputs (EPWMxA and EPWMxB) that can be used in the following configurations:
 - Two independent PWM outputs with single-edge operation
 - Two independent PWM outputs with dual-edge symmetric operation
 - One independent PWM output with dual-edge asymmetric operation
- Asynchronous override control of PWM signals through software.
- Programmable phase-control support for lag or lead operation relative to other ePWM modules.
- Hardware-locked (synchronized) phase relationship on a cycle-by-cycle basis.
- Dead-band generation with independent rising and falling edge delay control.
- Programmable trip zone allocation of both cycle-by-cycle trip and one-shot trip on fault conditions.
- A trip condition can force either high, low, or high-impedance state logic levels at PWM outputs.
- All events can trigger both CPU interrupts and ADC start of conversion (SOC)
- Programmable event prescaling minimizes CPU overhead on interrupts.
- PWM chopping by high-frequency carrier signal, useful for pulse transformer gate drives.

Each ePWM module is connected to the input/output signals shown in [Figure 19-1](#). The signals are described in detail in subsequent sections.

Each ePWM module consists of eight submodules and is connected within a system via the signals shown in [Figure 19-2](#).

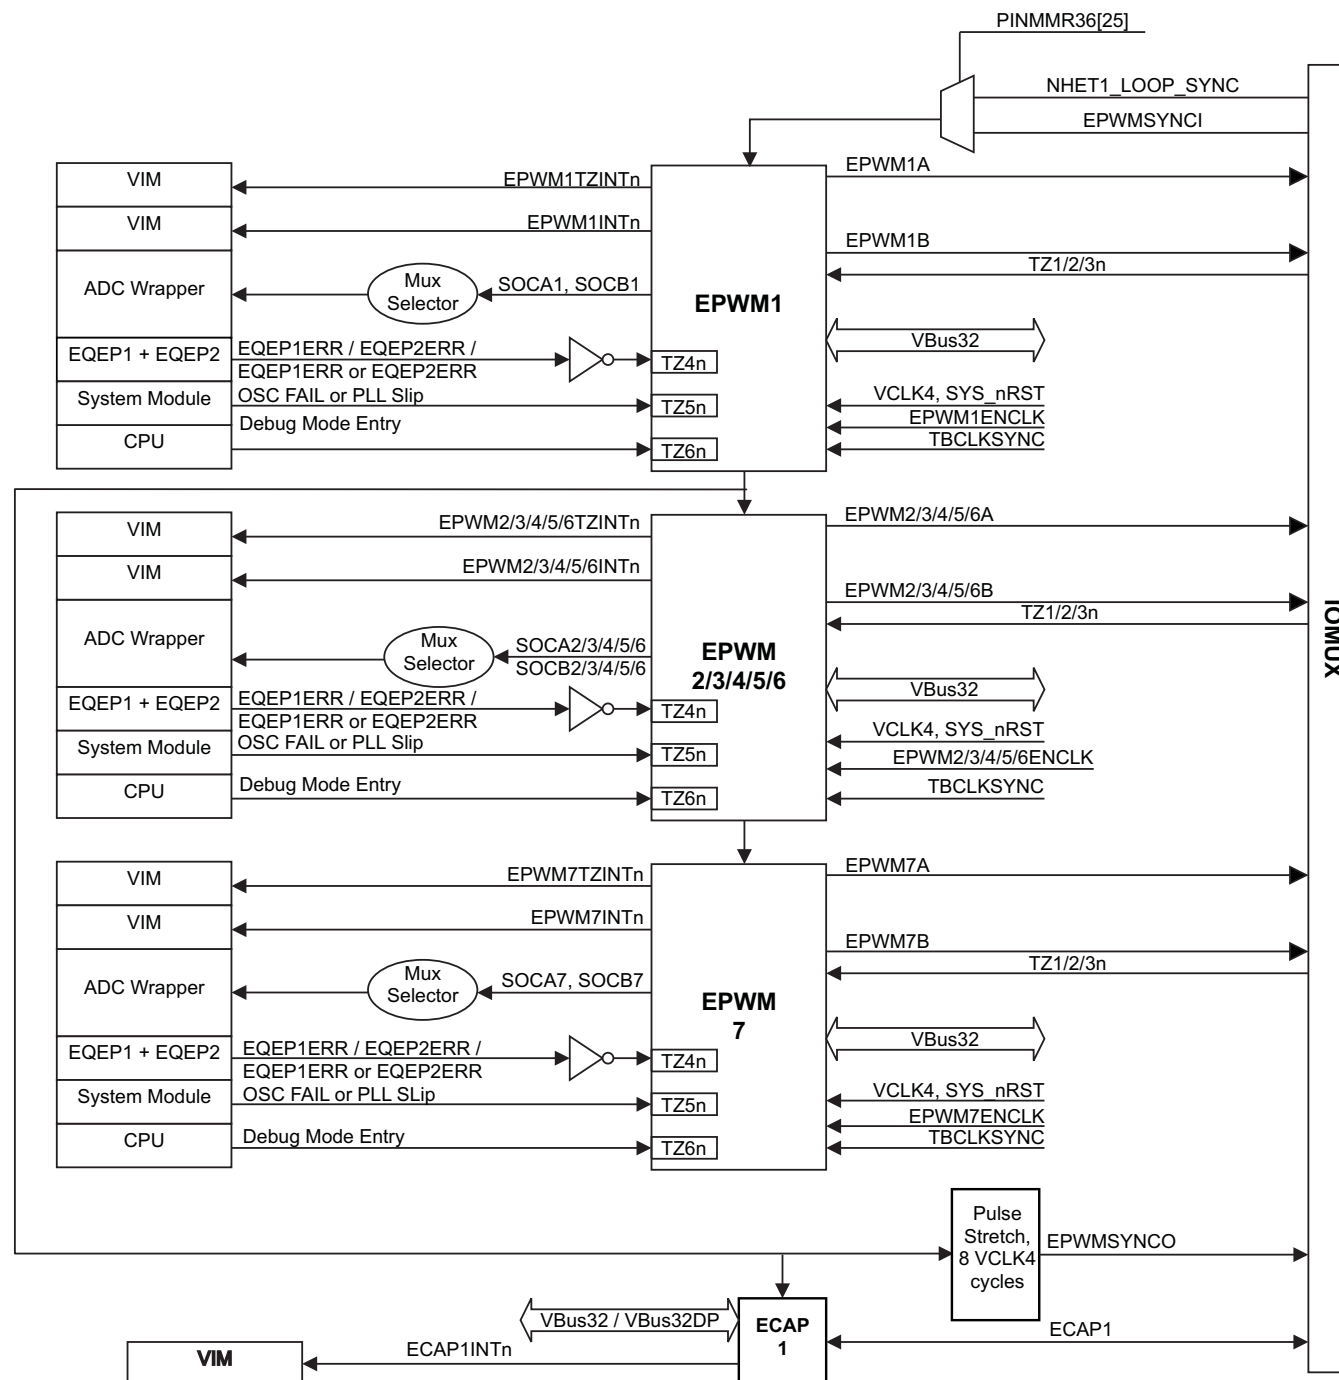

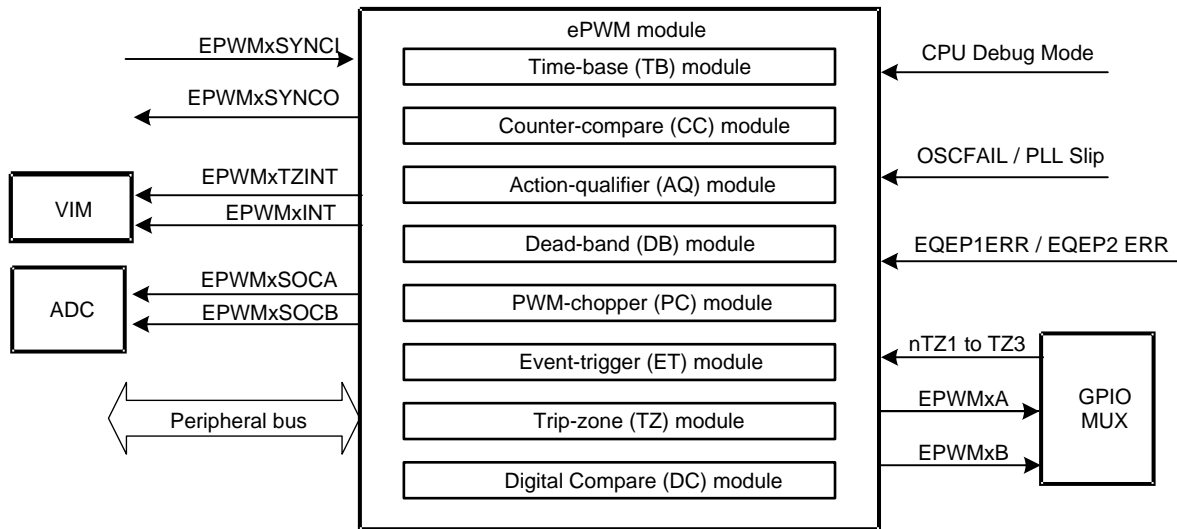

Figure 19-1. Multiple ePWM Modules

Figure 19-2. Submodules and Signal Connections for an ePWM Module

The main signals used by the ePWM module are:

- **PWM output signals (EPWMxA and EPWMxB).**

The PWM output signals are made available external to the device through the I/O Multiplexing Module (IOMM) as described in the IOMM chapter of the device's technical reference manual.

- **Trip-zone signals ($\overline{TZ1}$ to $\overline{TZ6}$).**

These input signals alert the ePWM module of fault conditions external to the ePWM module. Each ePWM module can be configured to either use or ignore any of the trip-zone signals. The $\overline{TZ1}$ to $\overline{TZ3}$ trip-zone signals can be configured as asynchronous inputs, or double-synchronized using VCLK4, or double-synchronized and filtered through a 6-VCLK4-cycle counter before connecting to the ePWM modules. This selection is done by configuring registers in the IOMM. $\overline{TZ4}$ is connected to an inverted eQEP1 error signal (EQEP1ERR), or to an inverted eQEP2 error signal (EQEP2ERR), or an OR-combination of EQEP1ERR and EQEP2ERR. This selection is also done via the IOMM registers. $\overline{TZ5}$ is connected to the system clock fail status. This is asserted whenever an oscillator failure is detected, or a PLL slip is detected. $\overline{TZ6}$ is connected to the debug mode entry indicator output from the CPU. This allows you to configure a trip action when the CPU halts.

- **Time-base synchronization input (EPWMxSYNCl) and output (EPWMxSYNCO) signals.**

The synchronization signals daisy chain the ePWM modules together. Each module can be configured to either use or ignore its synchronization input. The clock synchronization input and output signal are brought out to pins only for ePWM1 (ePWM module #1). The synchronization output for ePWM1 (EPWM1SYNCO) is also connected to the SYNCl of the first enhanced capture module (eCAP1).

- **ADC start-of-conversion signals (EPWMxSOCA and EPWMxSOCB).**

Each ePWM module has two ADC start of conversion signals. Any ePWM module can trigger a start of conversion. Which event triggers the start of conversion is configured in the Event-Trigger submodule of the ePWM.

- **Peripheral Bus**

The peripheral bus is 32-bits wide and allows both 16-bit and 32-bit writes to the ePWM register file.

19.1.2 Register Mapping

The complete ePWM module control and status register set is grouped by submodule as shown in [Table 19-1](#). Each register set is duplicated for each instance of the ePWM module. The start address for each ePWM register file instance on a device is specified in the specific part's datasheet.

Table 19-1. ePWM Module Control and Status Register Set Grouped by Submodule

19.2 ePWM Submodules

Eight submodules are included in every ePWM peripheral. Each of these submodules performs specific tasks that can be configured by software.

19.2.1 Overview

[Table 19-2](#) lists the eight key submodules together with a list of their main configuration parameters. For example, if you need to adjust or control the duty cycle of a PWM waveform, then you should see the counter-compare submodule in [Section 19.2.3](#) for relevant details.

Table 19-2. Submodule Configuration Parameters

| Submodule | Configuration Parameter or Option |
|----------------------|--|
| Time-base (TB) | <ul style="list-style-type: none"> Scale the time-base clock (TBCLK) relative to the system clock (VCLK4). Configure the PWM time-base counter (TBCTR) frequency or period. Set the mode for the time-base counter: <ul style="list-style-type: none"> count-up mode: used for asymmetric PWM count-down mode: used for asymmetric PWM count-up-and-down mode: used for symmetric PWM Configure the time-base phase relative to another ePWM module. Synchronize the time-base counter between modules through hardware or software. Configure the direction (up or down) of the time-base counter after a synchronization event. Configure how the time-base counter will behave when the device is halted by an emulator. Specify the source for the synchronization output of the ePWM module: <ul style="list-style-type: none"> Synchronization input signal Time-base counter equal to zero Time-base counter equal to counter-compare B (CMPB) No output synchronization signal generated. |
| Counter-compare (CC) | <ul style="list-style-type: none"> Specify the PWM duty cycle for output EPWMxA and/or output EPWMxB Specify the time at which switching events occur on the EPWMxA or EPWMxB output |

Table 19-2. Submodule Configuration Parameters (continued)

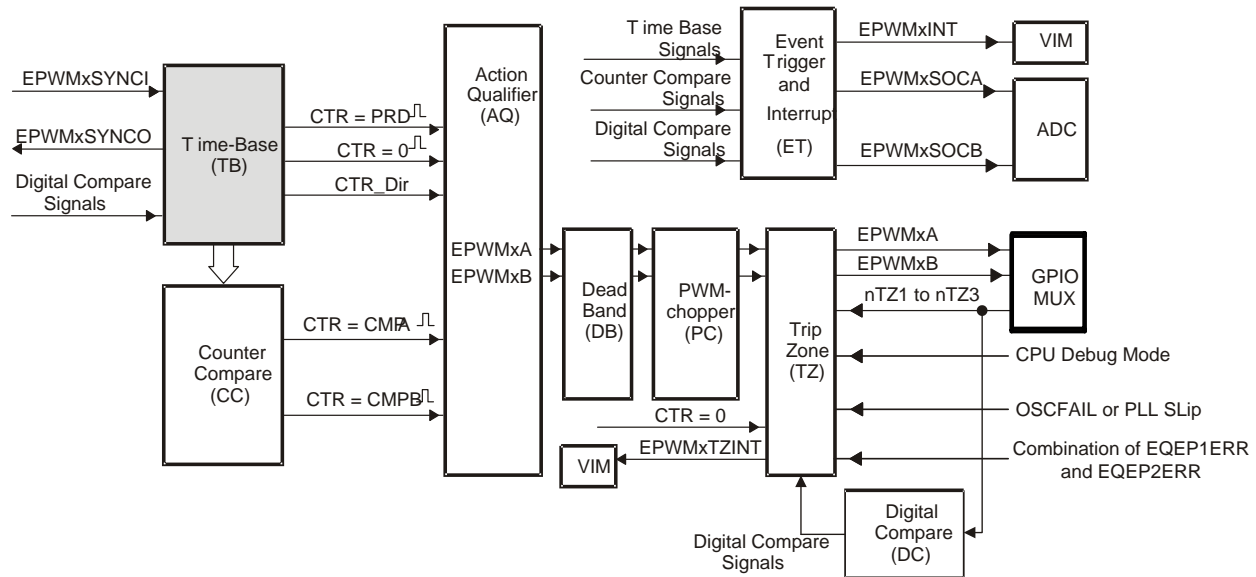

| Submodule | Configuration Parameter or Option |
|-----------------------|--|
| Action-qualifier (AQ) | <ul style="list-style-type: none"> Specify the type of action taken when a time-base or counter-compare submodule event occurs: <ul style="list-style-type: none"> No action taken Output EPWMxA and/or EPWMxB switched high Output EPWMxA and/or EPWMxB switched low Output EPWMxA and/or EPWMxB toggled Force the PWM output state through software control Configure and control the PWM dead-band through software |
| Dead-band (DB) | <ul style="list-style-type: none"> Control of traditional complementary dead-band relationship between upper and lower switches Specify the output rising-edge-delay value Specify the output falling-edge delay value Bypass the dead-band module entirely. In this case the PWM waveform is passed through without modification. Option to enable half-cycle clocking for double resolution. |
| PWM-chopper (PC) | <ul style="list-style-type: none"> Create a chopping (carrier) frequency. Pulse width of the first pulse in the chopped pulse train. Duty cycle of the second and subsequent pulses. Bypass the PWM-chopper module entirely. In this case the PWM waveform is passed through without modification. |
| Trip-zone (TZ) | <ul style="list-style-type: none"> Configure the ePWM module to react to one, all, or none of the trip-zone signals or digital compare events. Specify the tripping action taken when a fault occurs: <ul style="list-style-type: none"> Force EPWMxA and/or EPWMxB high Force EPWMxA and/or EPWMxB low Force EPWMxA and/or EPWMxB to a high-impedance state Configure EPWMxA and/or EPWMxB to ignore any trip condition. Configure how often the ePWM will react to each trip-zone signal: <ul style="list-style-type: none"> One-shot Cycle-by-cycle Enable the trip-zone to initiate an interrupt. Bypass the trip-zone module entirely. |
| Event-trigger (ET) | <ul style="list-style-type: none"> Enable the ePWM events that will trigger an interrupt. Enable ePWM events that will trigger an ADC start-of-conversion event. Specify the rate at which events cause triggers (every occurrence or every second or third occurrence) Poll, set, or clear event flags |
| Digital-compare (DC) | <ul style="list-style-type: none"> Enables trip zone signals to create events and filtered events Specify event-filtering options to capture TBCTR counter or generate blanking window |

Code examples are provided in the remainder of this document that show how to implement various ePWM module configurations. These examples use the constant definitions in the device *EPwm_defines.h* file in the device-specific header file and peripheral examples software package.

19.2.2 Time-Base (TB) Submodule

Each ePWM module has its own time-base submodule that determines all of the event timing for the ePWM module. Built-in synchronization logic allows the time-base of multiple ePWM modules to work together as a single system. Figure 19-3 illustrates the time-base module's place within the ePWM.

Figure 19-3. Time-Base Submodule Block Diagram

19.2.2.1 Purpose of the Time-Base Submodule

You can configure the time-base submodule for the following:

- Specify the ePWM time-base counter (TBCTR) frequency or period to control how often events occur.
- Manage time-base synchronization with other ePWM modules.
- Maintain a phase relationship with other ePWM modules.
- Set the time-base counter to count-up, count-down, or count-up-and-down mode.
- Generate the following events:
 - CTR = PRD: Time-base counter equal to the specified period (TBCTR = TBPRD) .
 - CTR = Zero: Time-base counter equal to zero (TBCTR = 0x0000).
- Configure the rate of the time-base clock; a prescaled version of the device peripheral clock domain (VCLK4). This allows the time-base counter to increment/decrement at a slower rate.

19.2.2.2 Controlling and Monitoring the Time-base Submodule

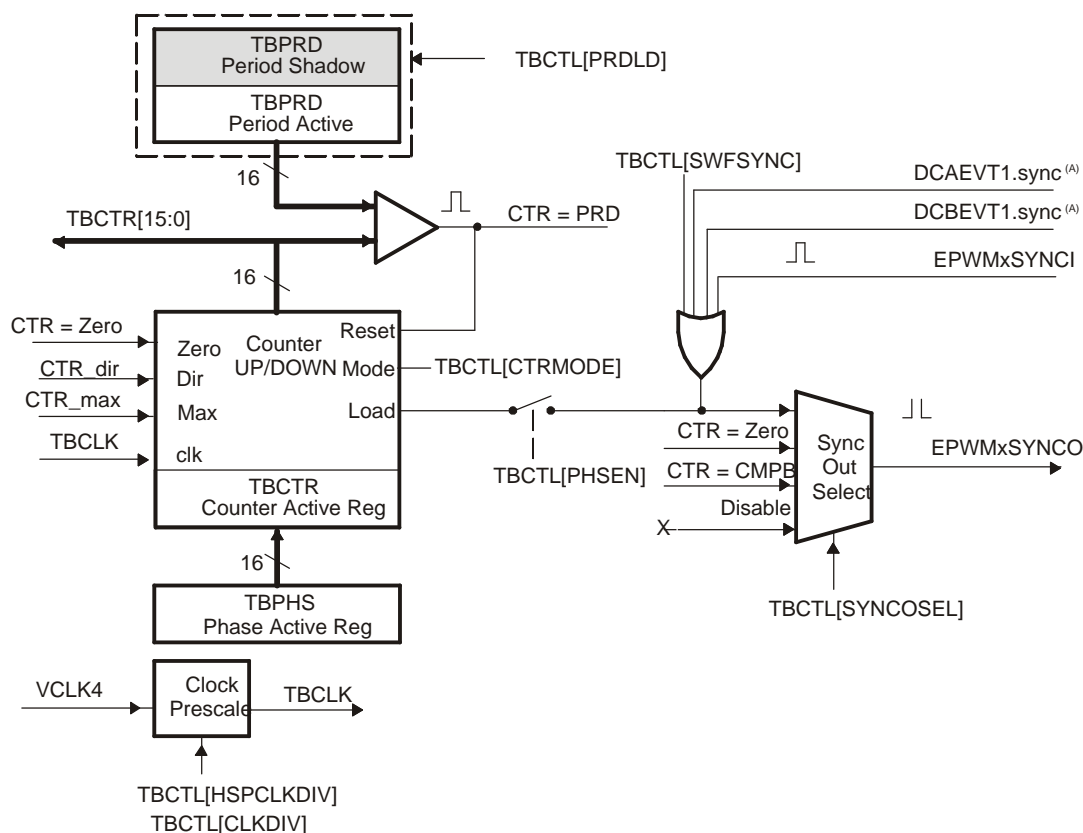

Table 19-3 shows the registers used to control and monitor the time-base submodule.

Table 19-3. Time-Base Submodule Registers

| Register Name | Address Offset | Shadowed | Description |
|---------------|----------------|----------|----------------------------|
| TBCTL | 0x0002 | No | Time-Base Control Register |
| TBSTS | 0x0000 | No | Time-Base Status Register |
| TBPHS | 0x0004 | No | Time-Base Phase Register |
| TBCTR | 0x000A | No | Time-Base Counter Register |
| TBPRD | 0x0008 | Yes | Time-Base Period Register |

The block diagram in Figure 19-4 shows the critical signals and registers of the time-base submodule. Table 19-4 provides descriptions of the key signals associated with the time-base submodule.

Figure 19-4. Time-Base Submodule Signals and Registers

A. These signals are generated by the digital compare (DC) submodule.

| Signal | Description |
|------------|--|
| EPWMxSYNCl | Time-base synchronization input. Input pulse used to synchronize the time-base counter with the counter of ePWM module earlier in the synchronization chain. An ePWM peripheral can be configured to use or ignore this signal. For the first ePWM module (EPWM1), this signal comes from a device pin or from the N2HET1 module. For subsequent ePWM modules, this signal is passed from another ePWM peripheral. For example, EPWM2SYNCl is generated by the ePWM1 peripheral, EPWM3SYNCl is generated by ePWM2 and so forth. See Section 19.2.2.3.3 for information on the synchronization order of a particular device. |
| EPWMxSYNCO | Time-base synchronization output. This output pulse is used to synchronize the counter of an ePWM module later in the synchronization chain. The ePWM module generates this signal from one of three event sources: <ol style="list-style-type: none"> 1. EPWMxSYNCl (Synchronization input pulse) 2. CTR = Zero: The time-base counter equal to zero (TBCTR = 0x0000). 3. CTR = CMPB: The time-base counter equal to the counter-compare B (TBCTR = CMPB) register. |
| CTR = PRD | Time-base counter equal to the specified period. This signal is generated whenever the counter value is equal to the active period register value. That is when TBCTR = TBPRD. |
| CTR = Zero | Time-base counter equal to zero This signal is generated whenever the counter value is zero. That is when TBCTR equals 0x0000. |
| CTR = CMPB | Time-base counter equal to active counter-compare B register (TBCTR = CMPB). This event is generated by the counter-compare submodule and used by the synchronization out logic |
| CTR_dir | Time-base counter direction. Indicates the current direction of the ePWM's time-base counter. This signal is high when the counter is increasing and low when it is decreasing. |
| CTR_max | Time-base counter equal max value. (TBCTR = 0xFFFF) Generated event when the TBCTR value reaches its maximum value. This signal is only used only as a status bit |
| TBCLK | Time-base clock. This is a prescaled version of the system clock (VCLK4) and is used by all submodules within the ePWM. This clock determines the rate at which time-base counter increments or decrements. |

19.2.2.3 Calculating PWM Period and Frequency

The frequency of PWM events is controlled by the time-base period (TBPRD) register and the mode of the time-base counter. Figure 19-5 shows the period (T_{pwm}) and frequency (F_{pwm}) relationships for the up-count, down-count, and up-down-count time-base counter modes when the period is set to 4 (TBPRD = 4). The time increment for each step is defined by the time-base clock (TBCLK) which is a prescaled version of the system clock (VCLK4).

The time-base counter has three modes of operation selected by the time-base control register (TBCTL):

- **Up-Down-Count Mode:**

In up-down-count mode, the time-base counter starts from zero and increments until the period (TBPRD) value is reached. When the period value is reached, the time-base counter then decrements until it reaches zero. At this point the counter repeats the pattern and begins to increment.

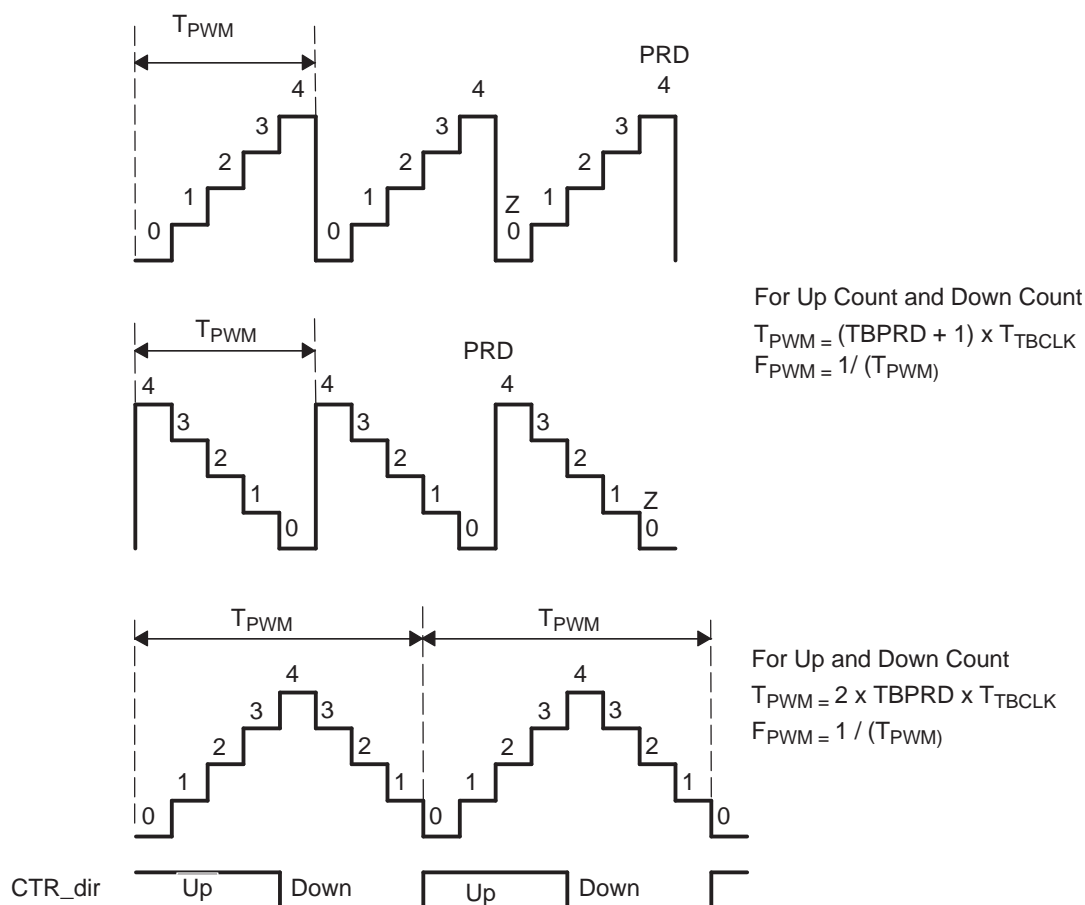

- **Up-Count Mode:**

In this mode, the time-base counter starts from zero and increments until it reaches the value in the period register (TBPRD). When the period value is reached, the time-base counter resets to zero and begins to increment once again.

- **Down-Count Mode:**

In down-count mode, the time-base counter starts from the period (TBPRD) value and decrements until it reaches zero. When it reaches zero, the time-base counter is reset to the period value and it begins to decrement once again.

Figure 19-5. Time-Base Frequency and Period

19.2.2.3.1 Time-Base Period Shadow Register

The time-base period register (TBPRD) has a shadow register. Shadowing allows the register update to be synchronized with the hardware. The following definitions are used to describe all shadow registers in the ePWM module:

- **Active Register**

The active register controls the hardware and is responsible for actions that the hardware causes or invokes.

- **Shadow Register**

The shadow register buffers or provides a temporary holding location for the active register. It has no direct effect on any control hardware. At a strategic point in time the shadow register's content is transferred to the active register. This prevents corruption or spurious operation due to the register being asynchronously modified by software.

The memory address of the shadow period register is the same as the active register. Which register is written to or read from is determined by the TBCTL[PRDL] bit. This bit enables and disables the TBPRD shadow register as follows:

- **Time-Base Period Shadow Mode:**

The TBPRD shadow register is enabled when TBCTL[PRDL] = 0. Reads from and writes to the TBPRD memory address go to the shadow register. The shadow register contents are transferred to the active register (TBPRD (Active) ← TBPRD (shadow)) when the time-base counter equals zero (TBCTR = 0x0000). By default the TBPRD shadow register is enabled.

- **Time-Base Period Immediate Load Mode:**

If immediate load mode is selected (TBCTL[PRDL] = 1), then a read from or a write to the TBPRD memory address goes directly to the active register.

19.2.2.3.2 Time-Base Clock Synchronization

Bit 1 of the device-level multiplexing control module (IOMM) register PINMMR37 is defined as the TBCLKSYNC bit. The TBCLKSYNC bit allows users to globally synchronize all enabled ePWM modules to the time-base clock (TBCLK). When set, all enabled ePWM module clocks are started with the first rising edge of TBCLK aligned. For perfectly synchronized TBCLKs, the prescalers for each ePWM module must be set identically.

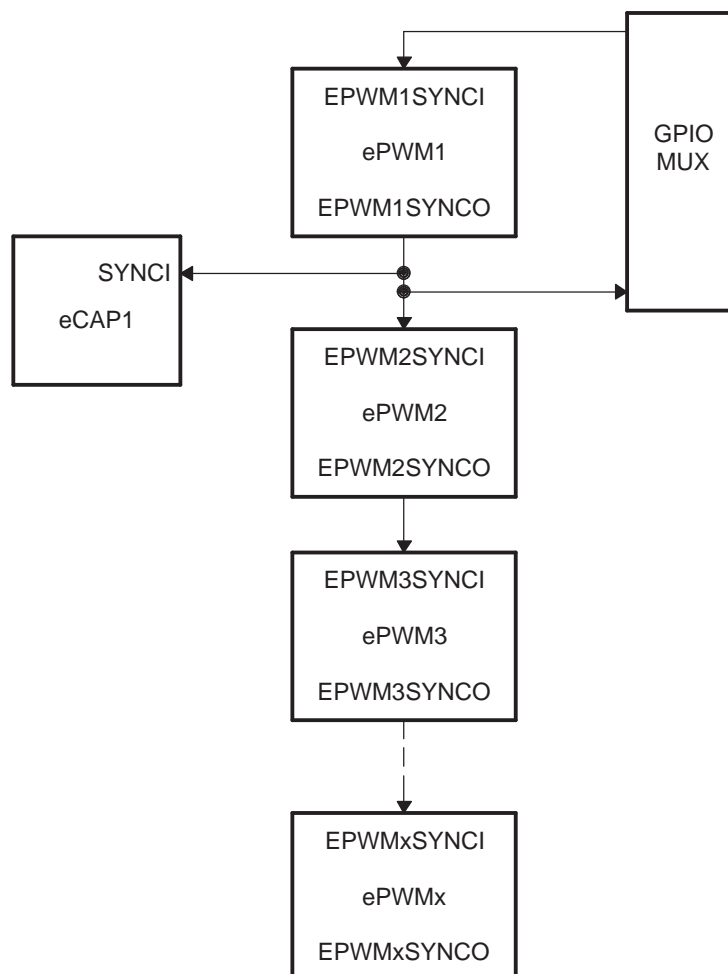

The proper procedure for enabling ePWM clocks is as follows:

1. Enable ePWM module clocks using the IOMM control registers for each ePWM module instance
2. Set TBCLKSYNC = 0. This will stop the time-base clock within any enabled ePWM module.
3. Configure ePWM modules: prescaler values and ePWM modes.
4. Set TBCLKSYNC = 1.

19.2.2.3.3 Time-Base Counter Synchronization

A time-base synchronization scheme connects all of the ePWM modules on a device. Each ePWM module has a synchronization input (EPWMxSYNCl) and a synchronization output (EPWMxSYNCO). The input synchronization for the first instance (ePWM1) comes from an external pin. The synchronization connections for the remaining ePWM modules are shown in Figure 19-6.

Figure 19-6. Time-Base Counter Synchronization Scheme

Each ePWM module can be configured to use or ignore the synchronization input. If the TBCTL[PHSEN] bit is set, then the time-base counter (TBCTR) of the ePWM module will be automatically loaded with the phase register (TBPHS) contents when one of the following conditions occur:

- **EPWMxSYNCl: Synchronization Input Pulse:**

The value of the phase register is loaded into the counter register when an input synchronization pulse is detected (TBPHS → TBCTR). This operation occurs on the next valid time-base clock (TBCLK) edge.

The delay from internal master module to slave modules is given by:

- if (TBCLK = VCLK4): $2 \times VCLK4$
- if (TBCLK != VCLK4): 1 TBCLK

- **Software Forced Synchronization Pulse:**

Writing a 1 to the TBCTL[SWFSYNC] control bit invokes a software forced synchronization. This pulse is ORed with the synchronization input signal, and therefore has the same effect as a pulse on EPWMxSYNCl.

- **Digital Compare Event Synchronization Pulse:**

DCAEVT1 and DCBEVT1 digital compare events can be configured to generate synchronization pulses which have the same affect as EPWMxSYNCl.

This feature enables the ePWM module to be automatically synchronized to the time base of another ePWM module. Lead or lag phase control can be added to the waveforms generated by different ePWM modules to synchronize them. In up-down-count mode, the TBCTL[PSHDIR] bit configures the direction of the time-base counter immediately after a synchronization event. The new direction is independent of the direction prior to the synchronization event. The PSHDIR bit is ignored in count-up or count-down modes. See [Figure 19-7](#) through [Figure 19-10](#) for examples.

Clearing the TBCTL[PHSEN] bit configures the ePWM to ignore the synchronization input pulse. The synchronization pulse can still be allowed to flow-through to the EPWMxSYNCO and be used to synchronize other ePWM modules. In this way, you can set up a master time-base (for example, ePWM1) and downstream modules (ePWM2 - ePWMx) may elect to run in synchronization with the master.

19.2.2.4 Phase Locking the Time-Base Clocks of Multiple ePWM Modules

The TBCLKSYNC bit can be used to globally synchronize the time-base clocks of all enabled ePWM modules on a device. When TBCLKSYNC = 0, the time-base clock of all ePWM modules is stopped (default). When TBCLKSYNC = 1, all ePWM time-base clocks are started with the rising edge of TBCLK aligned. For perfectly synchronized TBCLKs, the prescaler bits in the TBCTL register of each ePWM module must be set identically. The proper procedure for enabling the ePWM clocks is as follows:

1. Enable ePWM module clocks using the IOMM control registers for each ePWM module instance
2. Set TBCLKSYNC = 0. This will stop the time-base clock within any enabled ePWM module.
3. Configure ePWM modules: prescaler values and ePWM modes.
4. Set TBCLKSYNC = 1.

19.2.2.5 Time-Base Counter Modes and Timing Waveforms

The time-base counter operates in one of four modes:

- Up-count mode which is asymmetrical.
- Down-count mode which is asymmetrical.
- Up-down-count which is symmetrical
- Frozen where the time-base counter is held constant at the current value

To illustrate the operation of the first three modes, the following timing diagrams show when events are generated and how the time-base responds to an EPWMxSYNCl signal.

Figure 19-7. Time-Base Up-Count Mode Waveforms

Figure 19-8. Time-Base Down-Count Mode Waveforms

Figure 19-9. Time-Base Up-Down-Count Waveforms, TBCTL[PHSDIR = 0] Count Down On Synchronization Event

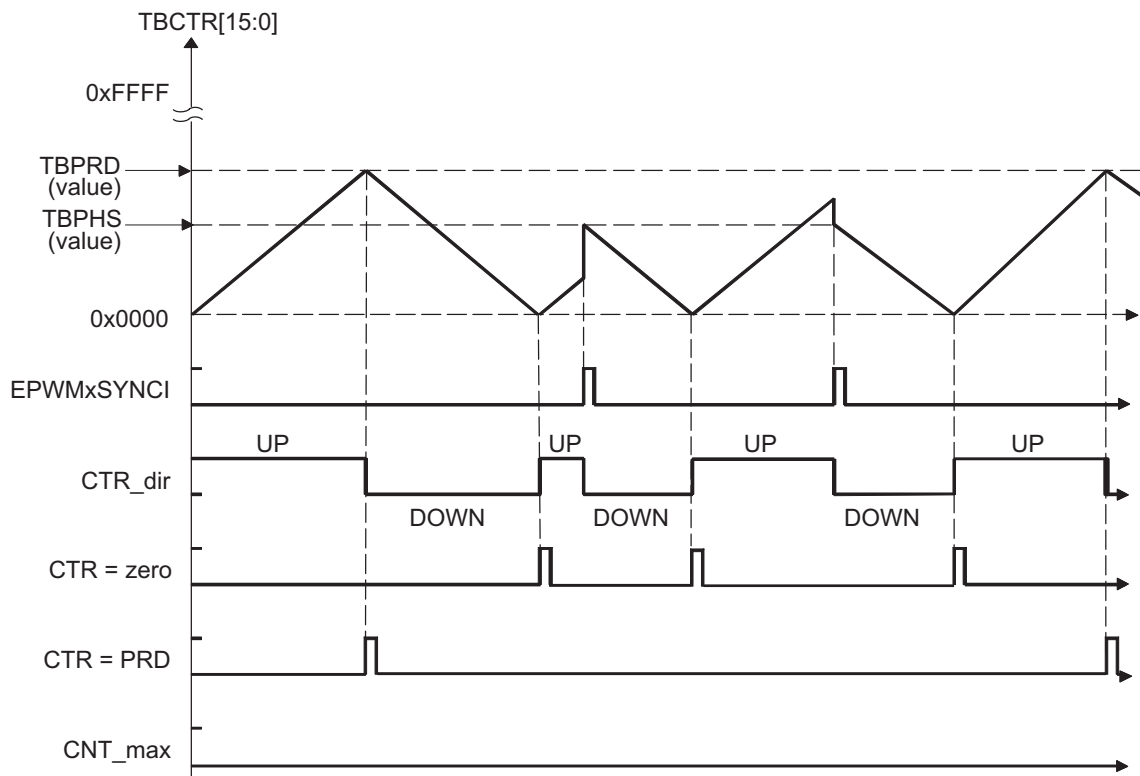

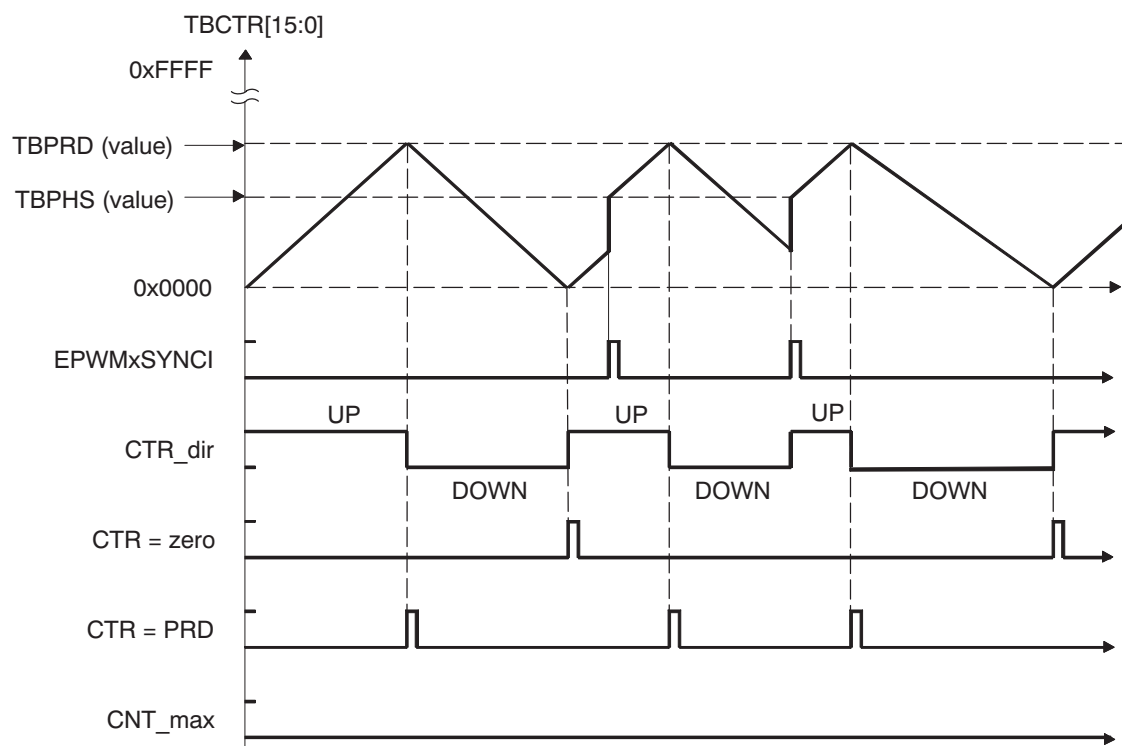

Figure 19-10. Time-Base Up-Down Count Waveforms, TBCTL[PHSDIR = 1] Count Up On Synchronization Event

19.2.3.1 Purpose of the Counter-Compare Submodule

The counter-compare submodule takes as input the time-base counter value. This value is continuously compared to the counter-compare A (CMPA) and counter-compare B (CMPB) registers. When the time-base counter is equal to one of the compare registers, the counter-compare unit generates an appropriate event.

The counter-compare:

- Generates events based on programmable time stamps using the CMPA and CMPB registers
 - CTR = CMPA: Time-base counter equals counter-compare A register (TBCTR = CMPA).
 - CTR = CMPB: Time-base counter equals counter-compare B register (TBCTR = CMPB)
- Controls the PWM duty cycle if the action-qualifier submodule is configured appropriately
- Shadows new compare values to prevent corruption or glitches during the active PWM cycle

19.2.3.2 Controlling and Monitoring the Counter-Compare Submodule

The counter-compare submodule operation is controlled and monitored by the registers shown in [Table 19-5](#):

Table 19-5. Counter-Compare Submodule Registers

| Register Name | Address Offset | Shadowed | Description |
|---------------|----------------|----------|-----------------------------------|
| CMPCTL | 0x000C | No | Counter-Compare Control Register. |
| CMPA | 0x0010 | Yes | Counter-Compare A Register |
| CMPB | 0x0016 | Yes | Counter-Compare B Register |

The key signals associated with the counter-compare submodule are described in [Table 19-6](#).

Table 19-6. Counter-Compare Submodule Key Signals

| Signal | Description of Event | Registers Compared |
|------------|---|--------------------|
| CTR = CMPA | Time-base counter equal to the active counter-compare A value | TBCTR = CMPA |
| CTR = CMPB | Time-base counter equal to the active counter-compare B value | TBCTR = CMPB |
| CTR = PRD | Time-base counter equal to the active period. Used to load active counter-compare A and B registers from the shadow register | TBCTR = TBPRD |
| CTR = ZERO | Time-base counter equal to zero. Used to load active counter-compare A and B registers from the shadow register | TBCTR = 0x0000 |

19.2.3.3 Operational Highlights for the Counter-Compare Submodule

The counter-compare submodule is responsible for generating two independent compare events based on two compare registers:

1. CTR = CMPA: Time-base counter equal to counter-compare A register (TBCTR = CMPA).
2. CTR = CMPB: Time-base counter equal to counter-compare B register (TBCTR = CMPB).

For up-count or down-count mode, each event occurs only once per cycle. For up-down-count mode each event occurs twice per cycle if the compare value is between 0x0000-TBPRD and once per cycle if the compare value is equal to 0x0000 or equal to TBPRD. These events are fed into the action-qualifier submodule where they are qualified by the counter direction and converted into actions if enabled. Refer to [Section 19.2.4.1](#) for more details.

The counter-compare registers CMPA and CMPB each have an associated shadow register. Shadowing provides a way to keep updates to the registers synchronized with the hardware. When shadowing is used, updates to the active registers only occur at strategic points. This prevents corruption or spurious operation due to the register being asynchronously modified by software. The memory address of the active register and the shadow register is identical. Which register is written to or read from is determined by the CMPCTL[SHDWAMODE] and CMPCTL[SHDWBMODE] bits. These bits enable and disable the CMPA shadow register and CMPB shadow register respectively. The behavior of the two load modes is described below:

Shadow Mode:

The shadow mode for the CMPA is enabled by clearing the CMPCTL[SHDWAMODE] bit and the shadow register for CMPB is enabled by clearing the CMPCTL[SHDWBMODE] bit. Shadow mode is enabled by default for both CMPA and CMPB.

If the shadow register is enabled then the content of the shadow register is transferred to the active register on one of the following events as specified by the CMPCTL[LOADAMODE] and CMPCTL[LOADBMODE] register bits:

- CTR = PRD: Time-base counter equal to the period (TBCTR = TBPRD).
- CTR = Zero: Time-base counter equal to zero (TBCTR = 0x0000)
- Both CTR = PRD and CTR = Zero

Only the active register contents are used by the counter-compare submodule to generate events to be sent to the action-qualifier.

Immediate Load Mode:

If immediate load mode is selected (that is, TBCTL[SHADWAMODE] = 1 or TBCTL[SHADWBMODE] = 1), then a read from or a write to the register will go directly to the active register.

19.2.3.4 Count Mode Timing Waveforms

The counter-compare module can generate compare events in all three count modes:

- Up-count mode: used to generate an asymmetrical PWM waveform.
- Down-count mode: used to generate an asymmetrical PWM waveform.
- Up-down-count mode: used to generate a symmetrical PWM waveform.

To best illustrate the operation of the first three modes, the timing diagrams in [Figure 19-13](#) through [Figure 19-16](#) show when events are generated and how the EPWMxSYNCl signal interacts.

Figure 19-13. Counter-Compare Event Waveforms in Up-Count Mode

NOTE: An EPWMxSYNCl external synchronization event can cause a discontinuity in the TBCTR count sequence. This can lead to a compare event being skipped. This skipping is considered normal operation and must be taken into account.

Figure 19-14. Counter-Compare Events in Down-Count Mode

Figure 19-15. Counter-Compare Events In Up-Down-Count Mode, TBCTL[PHSDIR = 0] Count Down On Synchronization Event

Figure 19-16. Counter-Compare Events In Up-Down-Count Mode, TBCTL[PHSDIR = 1] Count Up On Synchronization Event

19.2.4 Action-Qualifier (AQ) Submodule

Figure 19-17 shows the action-qualifier (AQ) submodule (see shaded block) in the ePWM system.

The action-qualifier submodule has the most important role in waveform construction and PWM generation. It decides which events are converted into various action types, thereby producing the required switched waveforms at the EPWMxA and EPWMxB outputs.

Figure 19-17. Action-Qualifier Submodule

19.2.4.1 Purpose of the Action-Qualifier Submodule

The action-qualifier submodule is responsible for the following:

- Qualifying and generating actions (set, clear, toggle) based on the following events:
 - CTR = PRD: Time-base counter equal to the period (TBCTR = TBPRD)
 - CTR = Zero: Time-base counter equal to zero (TBCTR = 0x0000)
 - CTR = CMPA: Time-base counter equal to the counter-compare A register (TBCTR = CMPA)
 - CTR = CMPB: Time-base counter equal to the counter-compare B register (TBCTR = CMPB)
- Managing priority when these events occur concurrently
- Providing independent control of events when the time-base counter is increasing and when it is decreasing

19.2.4.2 Action-Qualifier Submodule Control and Status Register Definitions

The action-qualifier submodule operation is controlled and monitored via the registers in Table 19-7.

Table 19-7. Action-Qualifier Submodule Registers

| Register Name | Address Offset | Shadowed | Description |
|---------------|----------------|----------|---|
| AQCTLA | 0x0014 | No | Action-Qualifier Control Register For Output A (EPWMxA) |
| AQCTLB | 0x001A | No | Action-Qualifier Control Register For Output B (EPWMxB) |
| AQSFRC | 0x0018 | No | Action-Qualifier Software Force Register |
| AQCSFRC | 0x001E | Yes | Action-Qualifier Continuous Software Force |

The action-qualifier submodule is based on event-driven logic. It can be thought of as a programmable cross switch with events at the input and actions at the output, all of which are software controlled via the set of registers shown in [Table 19-7](#).

Figure 19-18. Action-Qualifier Submodule Inputs and Outputs

For convenience, the possible input events are summarized again in [Table 19-8](#).

Table 19-8. Action-Qualifier Submodule Possible Input Events

| Signal | Description | Registers Compared |
|-----------------------|--|--------------------|
| CTR = PRD | Time-base counter equal to the period value | TBCTR = TBPRD |
| CTR = Zero | Time-base counter equal to zero | TBCTR = 0x0000 |
| CTR = CMPA | Time-base counter equal to the counter-compare A | TBCTR = CMPA |
| CTR = CMPB | Time-base counter equal to the counter-compare B | TBCTR = CMPB |
| Software forced event | Asynchronous event initiated by software | |

The software forced action is a useful asynchronous event. This control is handled by registers AQSFR and AQCSFRC.

The action-qualifier submodule controls how the two outputs EPWMxA and EPWMxB behave when a particular event occurs. The event inputs to the action-qualifier submodule are further qualified by the counter direction (up or down). This allows for independent action on outputs on both the count-up and count-down phases.

The possible actions imposed on outputs EPWMxA and EPWMxB are:

- **Set High:**
Set output EPWMxA or EPWMxB to a high level.
- **Clear Low:**
Set output EPWMxA or EPWMxB to a low level.
- **Toggle:**
If EPWMxA or EPWMxB is currently pulled high, then pull the output low. If EPWMxA or EPWMxB is currently pulled low, then pull the output high.
- **Do Nothing:**
Keep outputs EPWMxA and EPWMxB at same level as currently set. Although the "Do Nothing" option prevents an event from causing an action on the EPWMxA and EPWMxB outputs, this event can still trigger interrupts and ADC start of conversion. See the Event-trigger Submodule description in [Section 19.2.8](#) for details.

Actions are specified independently for either output (EPWMxA or EPWMxB). Any or all events can be configured to generate actions on a given output. For example, both CTR = CMPA and CTR = CMPB can operate on output EPWMxA. All qualifier actions are configured via the control registers found at the end of this section.

For clarity, the drawings in this document use a set of symbolic actions. These symbols are summarized in [Figure 19-19](#). Each symbol represents an action as a marker in time. Some actions are fixed in time (zero and period) while the CMPA and CMPB actions are moveable and their time positions are programmed via the counter-compare A and B registers, respectively. To turn off or disable an action, use the "Do Nothing option"; it is the default at reset.

Figure 19-19. Possible Action-Qualifier Actions for EPWMxA and EPWMxB Outputs

| S/W force | TB Counter equals: | | | | Actions |
|---|---|---|---|---|------------|
| | Zero | Comp A | Comp B | Period | |
|  |  |  |  |  | Do Nothing |
|  |  |  |  |  | Clear Low |
|  |  |  |  |  | Set High |
|  |  |  |  |  | Toggle |

19.2.4.3 Action-Qualifier Event Priority

It is possible for the ePWM action qualifier to receive more than one event at the same time. In this case events are assigned a priority by the hardware. The general rule is events occurring later in time have a higher priority and software forced events always have the highest priority. The event priority levels for up-down-count mode are shown in [Table 19-9](#). A priority level of 1 is the highest priority and level 7 is the lowest. The priority changes slightly depending on the direction of TBCTR.

Table 19-9. Action-Qualifier Event Priority for Up-Down-Count Mode

| Priority Level | Event If TBCTR is Incrementing TBCTR = Zero up to TBCTR = TBPRD | Event If TBCTR is Decrementing TBCTR = TBPRD down to TBCTR = 1 |
|----------------|--|---|
| 1 (Highest) | Software forced event | Software forced event |
| 2 | Counter equals CMPB on up-count (CBU) | Counter equals CMPB on down-count (CBD) |
| 3 | Counter equals CMPA on up-count (CAU) | Counter equals CMPA on down-count (CAD) |
| 4 | Counter equals zero | Counter equals period (TBPRD) |
| 5 | Counter equals CMPB on down-count (CBD) | Counter equals CMPB on up-count (CBU) |
| 6 (Lowest) | Counter equals CMPA on down-count (CAD) | Counter equals CMPA on up-count (CBU) |

[Table 19-10](#) shows the action-qualifier priority for up-count mode. In this case, the counter direction is always defined as up and thus down-count events will never be taken.

Table 19-10. Action-Qualifier Event Priority for Up-Count Mode

| Priority Level | Event |
|----------------|---|
| 1 (Highest) | Software forced event |
| 2 | Counter equal to period (TBPRD) |
| 3 | Counter equal to CMPB on up-count (CBU) |
| 4 | Counter equal to CMPA on up-count (CAU) |
| 5 (Lowest) | Counter equal to Zero |

[Table 19-11](#) shows the action-qualifier priority for down-count mode. In this case, the counter direction is always defined as down and thus up-count events will never be taken.

Table 19-11. Action-Qualifier Event Priority for Down-Count Mode

| Priority Level | Event |
|----------------|---|
| 1 (Highest) | Software forced event |
| 2 | Counter equal to Zero |
| 3 | Counter equal to CMPB on down-count (CBD) |
| 4 | Counter equal to CMPA on down-count (CAD) |
| 5 (Lowest) | Counter equal to period (TBPRD) |

It is possible to set the compare value greater than the period. In this case the action will take place as shown in [Table 19-12](#).

Table 19-12. Behavior if CMPA/CMPB is Greater than the Period

| Counter Mode | Compare on Up-Count Event CAD/CBD | Compare on Down-Count Event CAD/CBD |
|--------------------|--|--|
| Up-Count Mode | <p>If $CMPA/CMPB \leq TBPRD$ period, then the event occurs on a compare match ($TBCTR = CMPA$ or $CMPB$).</p> <p>If $CMPA/CMPB > TBPRD$, then the event will not occur.</p> | Never occurs. |
| Down-Count Mode | Never occurs. | <p>If $CMPA/CMPB < TBPRD$, the event will occur on a compare match ($TBCTR = CMPA$ or $CMPB$).</p> <p>If $CMPA/CMPB \geq TBPRD$, the event will occur on a period match ($TBCTR = TBPRD$).</p> |
| Up-Down-Count Mode | <p>If $CMPA/CMPB < TBPRD$ and the counter is incrementing, the event occurs on a compare match ($TBCTR = CMPA$ or $CMPB$).</p> <p>If $CMPA/CMPB \geq TBPRD$, the event will occur on a period match ($TBCTR = TBPRD$).</p> | <p>If $CMPA/CMPB < TBPRD$ and the counter is decrementing, the event occurs on a compare match ($TBCTR = CMPA$ or $CMPB$).</p> <p>If $CMPA/CMPB \geq TBPRD$, the event occurs on a period match ($TBCTR = TBPRD$).</p> |

19.2.4.4 Waveforms for Common Configurations

NOTE: The waveforms in this document show the ePWMs behavior for a static compare register value. In a running system, the active compare registers (CMPA and CMPB) are typically updated from their respective shadow registers once every period. The user specifies when the update will take place; either when the time-base counter reaches zero or when the time-base counter reaches period. There are some cases when the action based on the new value can be delayed by one period or the action based on the old value can take effect for an extra period. Some PWM configurations avoid this situation. These include, but are not limited to, the following:

Use up-down-count mode to generate a symmetric PWM:

- If you load CMPA/CMPB on zero, then use CMPA/CMPB values greater than or equal to 1.
- If you load CMPA/CMPB on period, then use CMPA/CMPB values less than or equal to $TBPRD - 1$.

This means there will always be a pulse of at least one TBCLK cycle in a PWM period which, when very short, tend to be ignored by the system.

Use up-down-count mode to generate an asymmetric PWM:

- To achieve 50%-0% asymmetric PWM use the following configuration: Load CMPA/CMPB on period and use the period action to clear the PWM and a compare-up action to set the PWM. Modulate the compare value from 0 to TBPRD to achieve 50%-0% PWM duty.

When using up-count mode to generate an asymmetric PWM:

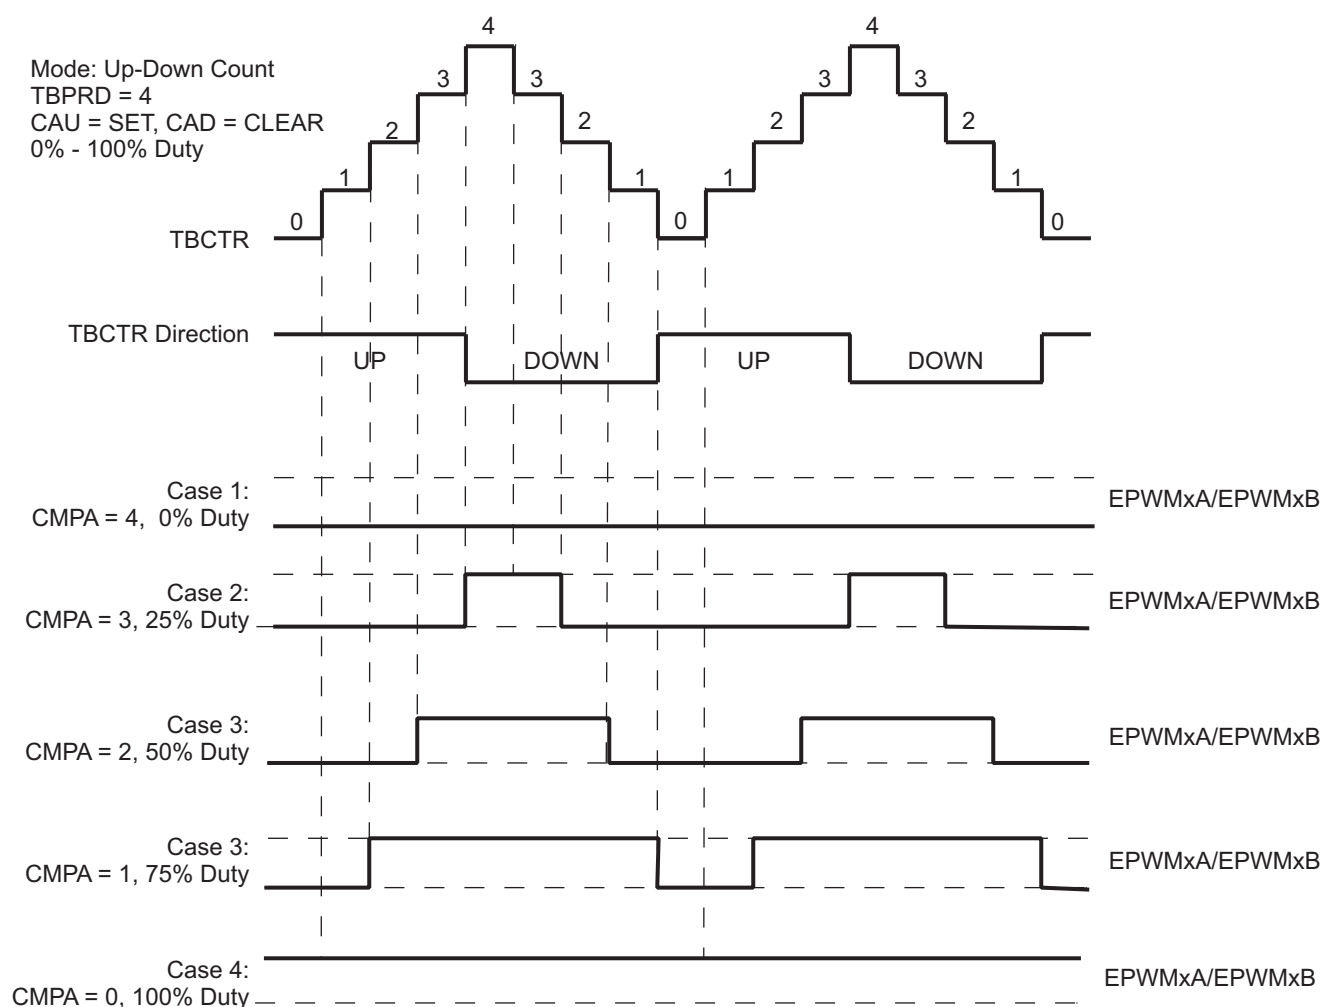

- To achieve 0-100% asymmetric PWM use the following configuration: Load CMPA/CMPB on TBPRD. Use the Zero action to set the PWM and a compare-up action to clear the PWM. Modulate the compare value from 0 to $TBPRD + 1$ to achieve 0-100% PWM duty.

See the *Using Enhanced Pulse Width Modulator (ePWM) Module for 0-100% Duty Cycle Control Application Report* ([SPRAA11](#))

Figure 19-20 shows how a symmetric PWM waveform can be generated using the up-down-count mode of the TBCTR. In this mode 0%-100% DC modulation is achieved by using equal compare matches on the up count and down count portions of the waveform. In the example shown, CMPA is used to make the comparison. When the counter is incrementing the CMPA match will pull the PWM output high. Likewise, when the counter is decrementing the compare match will pull the PWM signal low. When $CMPA = 0$, the PWM signal is low for the entire period giving the 0% duty waveform. When $CMPA = TBPRD$, the PWM signal is high achieving 100% duty.

When using this configuration in practice, if you load CMPA/CMPB on zero, then use CMPA/CMPB values greater than or equal to 1. If you load CMPA/CMPB on period, then use CMPA/CMPB values less than or equal to $TBPRD - 1$. This means there will always be a pulse of at least one TBCLK cycle in a PWM period which, when very short, tend to be ignored by the system.

Figure 19-20. Up-Down-Count Mode Symmetrical Waveform

The PWM waveforms in [Figure 19-21](#) through [Figure 19-26](#) show some common action-qualifier configurations. The C-code samples in [Example 19-1](#) through [Example 19-6](#) shows how to configure an ePWM module for each case. Some conventions used in the figures and examples are as follows:

- TBPRD, CMPA, and CMPB refer to the value written in their respective registers. The active register, not the shadow register, is used by the hardware.
- CMPx, refers to either CMPA or CMPB
- EPWMxA and EPWMxB refer to the output signals from ePWMx
- Up-Down means Count-up-and-down mode, Up means up-count mode and Dwn means down-count mode
- Sym = Symmetric, Asym = Asymmetric

Figure 19-21. Up, Single Edge Asymmetric Waveform, With Independent Modulation on EPWMxA and EPWMxB—Active High

- A $PWM\ period = (TBPRD + 1) \times T_{TBCLK}$
- B Duty modulation for EPWMxA is set by CMPA, and is active high (that is, high time duty proportional to CMPA).
- C Duty modulation for EPWMxB is set by CMPB and is active high (that is, high time duty proportional to CMPB).
- D The "Do Nothing" actions (X) are shown for completeness, but will not be shown on subsequent diagrams.
- E Actions at zero and period, although appearing to occur concurrently, are actually separated by one TBCLK period. TBCTR wraps from period to 0000.

[Example 19-1](#) contains a code sample showing initialization and run time for the waveforms in [Figure 19-21](#).

Example 19-1. Code Sample for [Figure 19-21](#)

```
// Initialization Time
// =====
EPwm1Regs.TBPRD = 600;                // Period = 601 TBCLK counts
EPwm1Regs.CMPA.half.CMPA = 350;      // Compare A = 350 TBCLK counts
EPwm1Regs.CMPB = 200;                // Compare B = 200 TBCLK counts
EPwm1Regs.TBPHS = 0;                 // Set Phase register to zero
EPwm1Regs.TBCTR = 0;                 // clear TB counter
EPwm1Regs.TBCTL.bit.CTRMODE = TB_COUNT_UP;
EPwm1Regs.TBCTL.bit.PHSEN = TB_DISABLE; // Phase loading disabled
EPwm1Regs.TBCTL.bit.PRDL = TB_SHADOW;
EPwm1Regs.TBCTL.bit.SYNCSEL = TB_SYNC_DISABLE;
EPwm1Regs.TBCTL.bit.HSPCLKDIV = TB_DIV1; // TBCLK = SYSCLK
EPwm1Regs.TBCTL.bit.CLKDIV = TB_DIV1;
EPwm1Regs.CMPCTL.bit.SHDWAMODE = CC_SHADOW;
EPwm1Regs.CMPCTL.bit.SHDWBMODE = CC_SHADOW;
EPwm1Regs.CMPCTL.bit.LOADAMODE = CC_CTR_ZERO; // load on CTR = Zero

EPwm1Regs.CMPB = EdgePosB;
```

19.2.5.3 Operational Highlights for the Dead-Band Submodule

The following sections provide the operational highlights.

The dead-band submodule has two groups of independent selection options as shown in [Figure 19-28](#).

- **Input Source Selection:**

The input signals to the dead-band module are the EPWMxA and EPWMxB output signals from the action-qualifier. In this section they will be referred to as EPWMxA In and EPWMxB In. Using the DBCTL[IN_MODE] control bits, the signal source for each delay, falling-edge or rising-edge, can be selected:

- EPWMxA In is the source for both falling-edge and rising-edge delay. This is the default mode.
- EPWMxA In is the source for falling-edge delay, EPWMxB In is the source for rising-edge delay.
- EPWMxA In is the source for rising edge delay, EPWMxB In is the source for falling-edge delay.
- EPWMxB In is the source for both falling-edge and rising-edge delay.

- **Half Cycle Clocking:**

The dead-band submodule can be clocked using half cycle clocking to double the resolution (that is, counter clocked at 2× TBCLK)

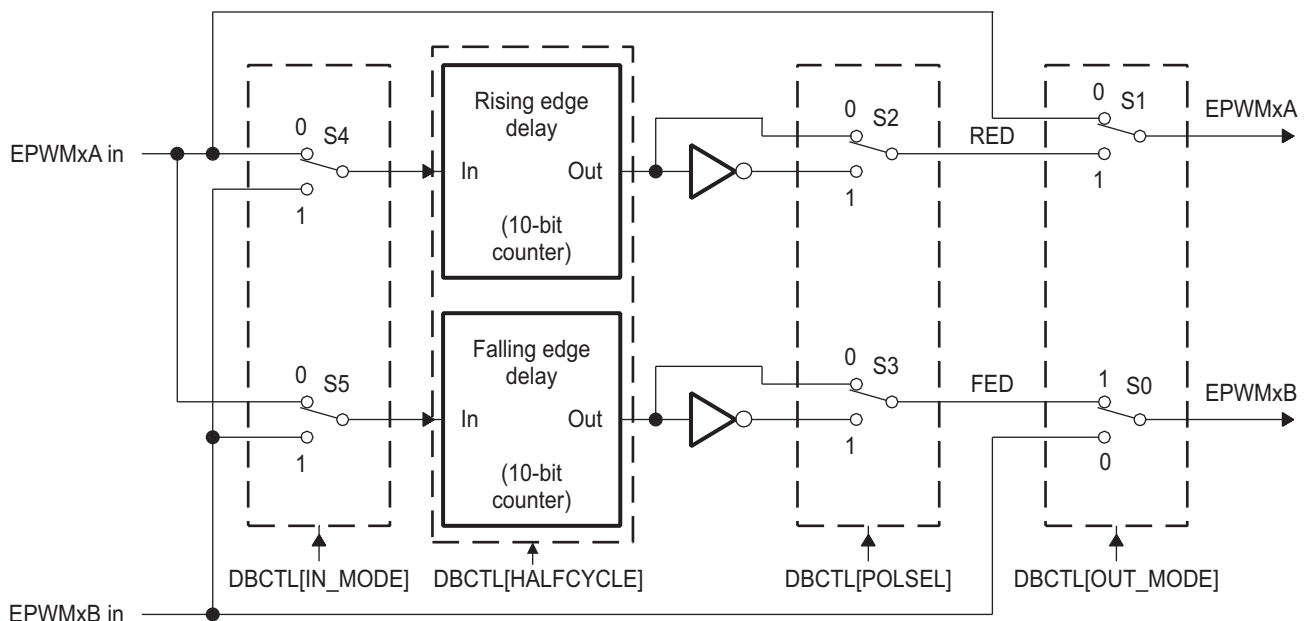

- **Output Mode Control:**

The output mode is configured by way of the DBCTL[OUT_MODE] bits. These bits determine if the falling-edge delay, rising-edge delay, neither, or both are applied to the input signals.

- **Polarity Control:**

The polarity control (DBCTL[POLSEL]) allows you to specify whether the rising-edge delayed signal and/or the falling-edge delayed signal is to be inverted before being sent out of the dead-band submodule.

Figure 19-28. Configuration Options for the Dead-Band Submodule

Although all combinations are supported, not all are typical usage modes. [Table 19-14](#) documents some classical dead-band configurations. These modes assume that the DBCTL[IN_MODE] is configured such that EPWMxA In is the source for both falling-edge and rising-edge delay. Enhanced, or non-traditional modes can be achieved by changing the input signal source. The modes shown in [Table 19-14](#) fall into the following categories:

- **Mode 1: Bypass both falling-edge delay (FED) and rising-edge delay (RED)**
Allows you to fully disable the dead-band submodule from the PWM signal path.
- **Mode 2-5: Classical Dead-Band Polarity Settings:**
These represent typical polarity configurations that should address all the active high/low modes required by available industry power switch gate drivers. The waveforms for these typical cases are shown in [Figure 19-29](#). Note that to generate equivalent waveforms to [Figure 19-29](#), configure the action-qualifier submodule to generate the signal as shown for EPWMxA.
- **Mode 6: Bypass rising-edge-delay and Mode 7: Bypass falling-edge-delay**
Finally the last two entries in [Table 19-14](#) show combinations where either the falling-edge-delay (FED) or rising-edge-delay (RED) blocks are bypassed.

Table 19-14. Classical Dead-Band Operating Modes

| Mode | Mode Description | DBCTL[POLSEL] | | DBCTL[OUT_MODE] | |
|------|---|---------------|--------|-----------------|----|
| | | S3 | S2 | S1 | S0 |
| 1 | EPWMxA and EPWMxB Passed Through (No Delay) | X | X | 0 | 0 |
| 2 | Active High Complementary (AHC) | 1 | 0 | 1 | 1 |
| 3 | Active Low Complementary (ALC) | 0 | 1 | 1 | 1 |
| 4 | Active High (AH) | 0 | 0 | 1 | 1 |
| 5 | Active Low (AL) | 1 | 1 | 1 | 1 |
| 6 | EPWMxA Out = EPWMxA In (No Delay) EPWMxB Out = EPWMxA In with Falling Edge Delay | 0 or 1 | 0 or 1 | 0 | 1 |
| 7 | EPWMxA Out = EPWMxA In with Rising Edge Delay EPWMxB Out = EPWMxB In with No Delay | 0 or 1 | 0 or 1 | 1 | 0 |

Figure 19-29 shows waveforms for typical cases where $0\% < \text{duty} < 100\%$.

Figure 19-29. Dead-Band Waveforms for Typical Cases ($0\% < \text{Duty} < 100\%$)

The dead-band submodule supports independent values for rising-edge (RED) and falling-edge (FED) delays. The amount of delay is programmed using the DBRED and DBFED registers. These are 10-bit registers and their value represents the number of time-base clock, TBCLK, periods a signal edge is delayed by. For example, the formula to calculate falling-edge-delay and rising-edge-delay are:

$$\text{FED} = \text{DBFED} \times T_{\text{TBCLK}}$$

$$\text{RED} = \text{DBRED} \times T_{\text{TBCLK}}$$

Where T_{TBCLK} is the period of TBCLK, the prescaled version of VCLK4.

For convenience, delay values for various TBCLK options are shown in [Table 19-15](#).

Table 19-15. Dead-Band Delay Values in μS as a Function of DBFED and DBRED

| Dead-Band Value | Dead-Band Delay in μS | | |
|-----------------|----------------------------------|---------------------|---------------------|
| DBFED, DBRED | TBCLK = VCLK4/1 | TBCLK = VCLK4 /2 | TBCLK = VCLK4/4 |
| 1 | 0.02 μS | 0.03 μS | 0.07 μS |
| 5 | 0.08 μS | 0.17 μS | 0.33 μS |
| 10 | 0.17 μS | 0.33 μS | 0.67 μS |
| 100 | 1.67 μS | 3.33 μS | 6.67 μS |
| 200 | 3.33 μS | 6.67 μS | 13.33 μS |
| 400 | 6.67 μS | 13.33 μS | 26.67 μS |
| 500 | 8.33 μS | 16.67 μS | 33.33 μS |
| 600 | 10.00 μS | 20.00 μS | 40.00 μS |
| 700 | 11.67 μS | 23.33 μS | 46.67 μS |
| 800 | 13.33 μS | 26.67 μS | 53.33 μS |
| 900 | 15.00 μS | 30.00 μS | 60.00 μS |
| 1000 | 16.67 μS | 33.33 μS | 66.67 μS |

When half-cycle clocking is enabled, the formula to calculate the falling-edge-delay and rising-edge-delay becomes:

$$\text{FED} = \text{DBFED} \times T_{\text{TBCLK}}/2$$

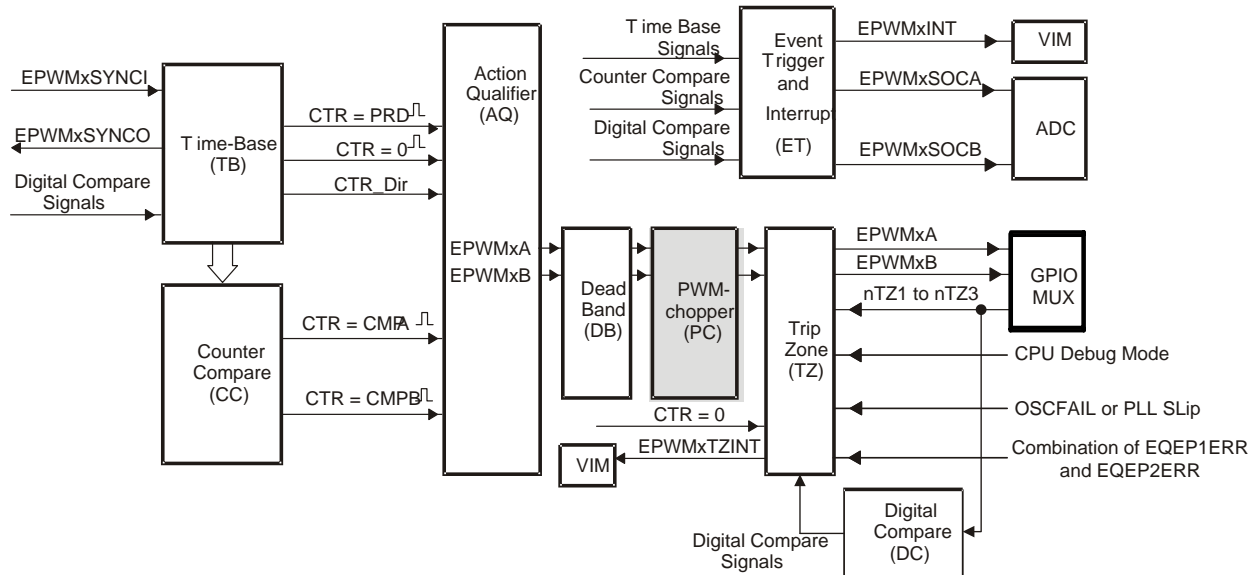

$$\text{RED} = \text{DBRED} \times T_{\text{TBCLK}}/2$$

19.2.6 PWM-Chopper (PC) Submodule

Figure 19-30 illustrates the PWM-chopper (PC) submodule within the ePWM module.

The PWM-chopper submodule allows a high-frequency carrier signal to modulate the PWM waveform generated by the action-qualifier and dead-band submodules. This capability is important if you need pulse transformer-based gate drivers to control the power switching elements.

Figure 19-30. PWM-Chopper Submodule

19.2.6.1 Purpose of the PWM-Chopper Submodule

The key functions of the PWM-chopper submodule are:

- Programmable chopping (carrier) frequency
- Programmable pulse width of first pulse
- Programmable duty cycle of second and subsequent pulses
- Can be fully bypassed if not required

19.2.6.2 Controlling the PWM-Chopper Submodule

The PWM-chopper submodule operation is controlled via the registers in Table 19-16.

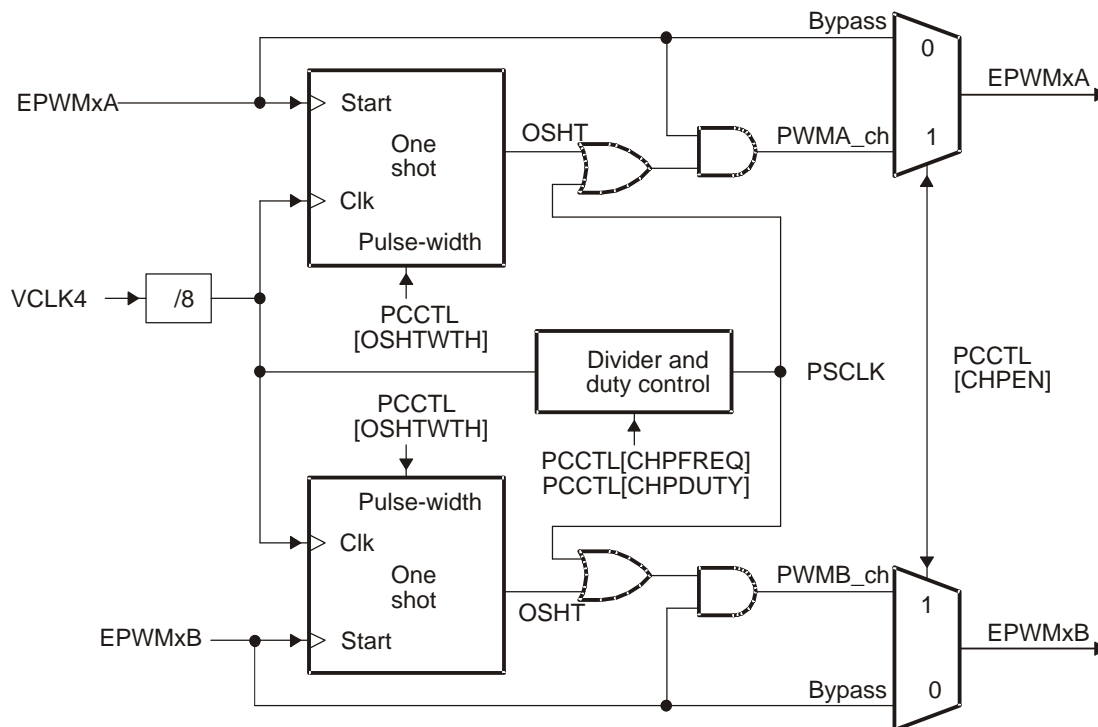

Table 19-16. PWM-Chopper Submodule Registers

| Register Name | Address Offset | Shadowed | Description |
|---------------|----------------|----------|------------------------------|
| PCCTL | 0x003E | No | PWM-chopper Control Register |

19.2.6.3 Operational Highlights for the PWM-Chopper Submodule

Figure 19-31 shows the operational details of the PWM-chopper submodule. The carrier clock is derived from VCLK4. Its frequency and duty cycle are controlled via the CHPFREQ and CHPDUTY bits in the PCCTL register. The one-shot block is a feature that provides a high energy first pulse to ensure hard and fast power switch turn on, while the subsequent pulses sustain pulses, ensuring the power switch remains on. The one-shot width is programmed via the OSHTWTH bits. The PWM-chopper submodule can be fully disabled (bypassed) via the CHPEN bit.

Figure 19-31. PWM-Chopper Submodule Operational Details

19.2.6.4 Waveforms

Figure 19-32 shows simplified waveforms of the chopping action only; one-shot and duty-cycle control are not shown. Details of the one-shot and duty-cycle control are discussed in the following sections.

Figure 19-32. Simple PWM-Chopper Submodule Waveforms Showing Chopping Action Only

19.2.6.4.1 One-Shot Pulse

The width of the first pulse can be programmed to any of 16 possible pulse width values. The width or period of the first pulse is given by:

$$T_{1\text{stpulse}} = T_{\text{VCLK4}} \times 8 \times \text{OSHTWTH}$$

Where T_{VCLK4} is the period of the system clock (VCLK4) and OSHTWTH is the four control bits (value from 1 to 16)

Figure 19-33 shows the first and subsequent sustaining pulses and Table 19-17 gives the possible pulse width values for a VCLK4 = 100 MHz.

Figure 19-33. PWM-Chopper Submodule Waveforms Showing the First Pulse and Subsequent Sustaining Pulses

Table 19-17. Possible Pulse Width Values for VCLK4 = 100 MHz

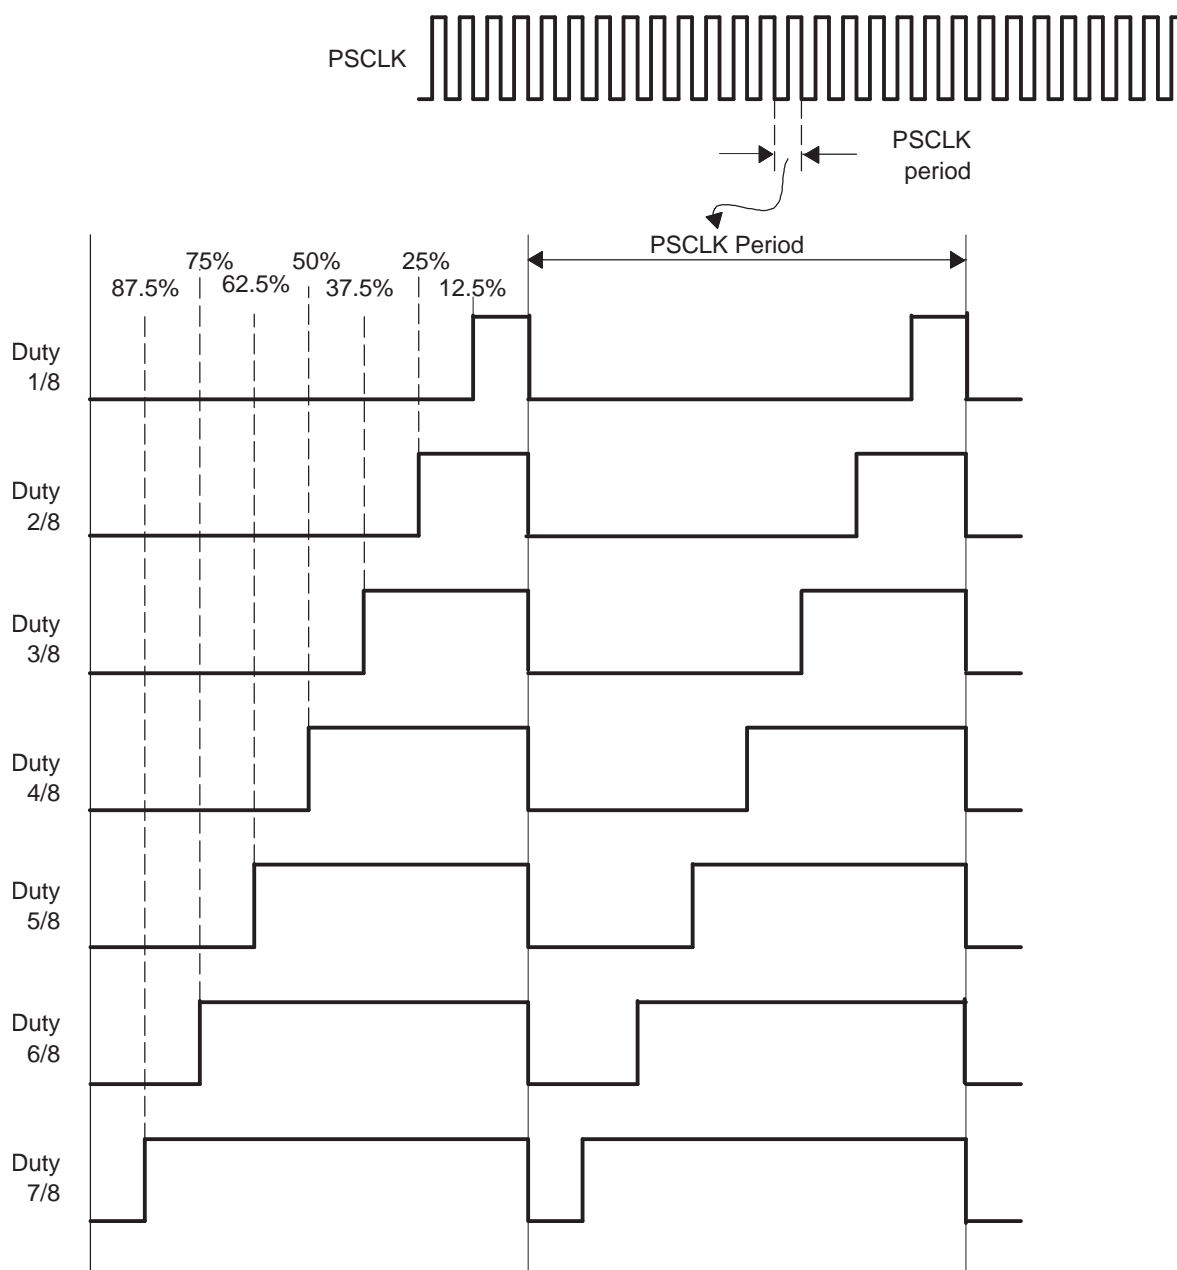

| OSHTWTHz (hex) | Pulse Width (nS) |
|-------------------|---------------------|
| 0 | 100 |
| 1 | 200 |
| 2 | 300 |
| 3 | 400 |
| 4 | 500 |
| 5 | 600 |
| 6 | 700 |
| 7 | 800 |
| 8 | 900 |
| 9 | 1000 |
| A | 1100 |
| B | 1200 |
| C | 1300 |
| D | 1400 |
| E | 1500 |
| F | 1600 |

19.2.6.4.2 Duty Cycle Control

Pulse transformer-based gate drive designs need to comprehend the magnetic properties or characteristics of the transformer and associated circuitry. Saturation is one such consideration. To assist the gate drive designer, the duty cycles of the second and subsequent pulses have been made programmable. These sustaining pulses ensure the correct drive strength and polarity is maintained on the power switch gate during the on period, and hence a programmable duty cycle allows a design to be tuned or optimized via software control.

Figure 19-34 shows the duty cycle control that is possible by programming the CHPDUTY bits. One of seven possible duty ratios can be selected ranging from 12.5% to 87.5%.

Figure 19-34. PWM-Chopper Submodule Waveforms Showing the Pulse Width (Duty Cycle) Control of Sustaining Pulses

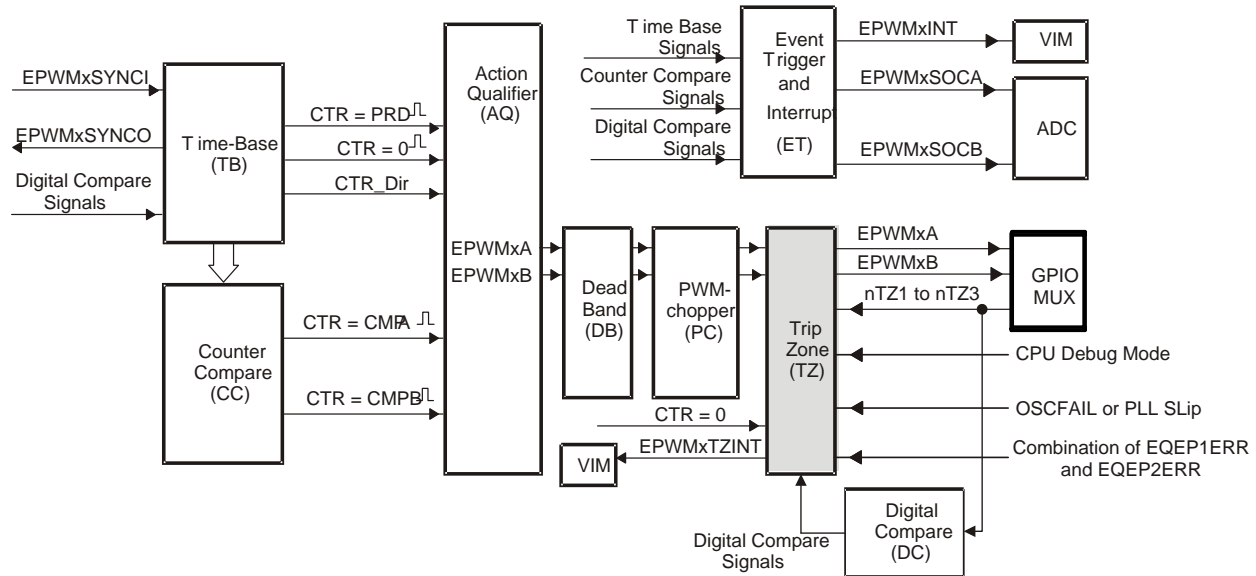

19.2.7 Trip-Zone (TZ) Submodule

Figure 19-35 shows how the trip-zone (TZ) submodule fits within the ePWM module.

Each ePWM module is connected to six \overline{TZn} signals ($\overline{TZ1}$ to $\overline{TZ6}$). $\overline{TZ1}$ to $\overline{TZ3}$ are sourced from the GPIO mux. $\overline{TZ4}$ is sourced from a combination of EQEP1ERR and EQEP2ERR signals. $\overline{TZ5}$ is connected to the system oscillator or PLL clock fail logic, and $\overline{TZ6}$ is sourced from the debug mode halt indication output from the CPU. These signals indicate fault or trip conditions, and the ePWM outputs can be programmed to respond accordingly when faults occur.

Figure 19-35. Trip-Zone Submodule

19.2.7.1 Purpose of the Trip-Zone Submodule

The key functions of the Trip-Zone submodule are:

- Trip inputs $\overline{TZ1}$ to $\overline{TZ6}$ are mapped to all ePWM modules.
- Upon a fault indication, either no action is taken or the ePWM outputs $EPWMxA$ and $EPWMxB$ can be forced to one of the following:
 - High
 - Low
 - High-impedance
- Support for one-shot trip (OSHT) for major short circuits or over-current conditions.
- Support for cycle-by-cycle tripping (CBC) for current limiting operation.
- Support for digital compare tripping (DC) based on state of on-chip analog comparator module outputs and/or $\overline{TZ1}$ to $\overline{TZ3}$ signals.
- Each trip-zone input and digital compare (DC) submodule DCAEVT1/2 or DCBEVT1/2 force event can be allocated to either one-shot or cycle-by-cycle operation.
- Interrupt generation is possible on any trip-zone input.
- Software-forced tripping is also supported.
- The trip-zone submodule can be fully bypassed if it is not required.

19.2.7.2 Controlling and Monitoring the Trip-Zone Submodule

The trip-zone submodule operation is controlled and monitored through the following registers:

Table 19-18. Trip-Zone Submodule Registers

| Register Name | Address Offset | Shadowed | Description ⁽¹⁾ |
|---------------|----------------|----------|--|
| TZSEL | 0x0026 | No | Trip-Zone Select Register |
| TZDCSEL | 0x0024 | No | Trip-zone Digital Compare Select Register ⁽²⁾ |
| TZCTL | 0x002A | No | Trip-Zone Control Register |
| TZEINT | 0x0028 | No | Trip-Zone Enable Interrupt Register |
| TZFLG | 0x002E | No | Trip-Zone Flag Register |
| TZCLR | 0x002C | No | Trip-Zone Clear Register |
| TZFRC | 0x0032 | No | Trip-Zone Force Register |

⁽¹⁾ All trip-zone registers are writable only in privileged mode.

⁽²⁾ This register is discussed in more detail in [Section 19.2.9](#).

19.2.7.3 Operational Highlights for the Trip-Zone Submodule

The following sections describe the operational highlights and configuration options for the trip-zone submodule.

The trip-zone signals $\overline{TZ1}$ to $\overline{TZ6}$ (also collectively referred to as \overline{TZn}) are active low input signals. When one of these signals goes low, or when a DCAEVT1/2 or DCBEVT1/2 force happens based on the TZDCSEL register event selection, it indicates that a trip event has occurred. Each ePWM module can be individually configured to ignore or use each of the trip-zone signals or DC events. Which trip-zone signals or DC events are used by a particular ePWM module is determined by the TZSEL register for that specific ePWM module. The trip-zone signals may or may not be synchronized to the system clock (VCLK4) and digitally filtered within the GPIO MUX block. A minimum of 3*TBCLK low pulse width on \overline{TZn} inputs is sufficient to trigger a fault condition on the ePWM module. If the pulse width is less than this, the trip condition may not be latched. The asynchronous trip makes sure that if clocks are missing for any reason, the outputs can still be tripped by a valid event present on \overline{TZn} inputs. The GPIOs or peripherals must be appropriately configured. For more information, see the IOMM chapter of the device technical reference manual.

Each \overline{TZn} input can be individually configured to provide either a cycle-by-cycle or one-shot trip event for an ePWM module. DCAEVT1 and DCBEVT1 events can be configured to directly trip an ePWM module or provide a one-shot trip event to the module. Likewise, DCAEVT2 and DCBEVT2 events can also be configured to directly trip an ePWM module or provide a cycle-by-cycle trip event to the module. This configuration is determined by the TZSEL[DCAEVT1/2], TZSEL[DCBEVT1/2], TZSEL[CBCn], and TZSEL[OSHTn] control bits (where n corresponds to the trip input) respectively.

- **Cycle-by-Cycle (CBC):**

When a cycle-by-cycle trip event occurs, the action specified in the TZCTL[TZA] and TZCTL[TZB] bits is carried out immediately on the EPWMxA and/or EPWMxB output. [Table 19-19](#) lists the possible actions. In addition, the cycle-by-cycle trip event flag (TZFLG[CBC]) is set and a EPWMx_TZINT interrupt is generated if it is enabled in the TZEINT register and VIM peripheral.

If the CBC interrupt is enabled via the TZEINT register, and DCAEVT2 or DCBEVT2 are selected as CBC trip sources via the TZSEL register, it is not necessary to also enable the DCAEVT2 or DCBEVT2 interrupts in the TZEINT register, as the DC events trigger interrupts through the CBC mechanism.

The specified condition on the inputs is automatically cleared when the ePWM time-base counter reaches zero (TBCTR = 0x0000) if the trip event is no longer present. Therefore, in this mode, the trip event is cleared or reset every PWM cycle. The TZFLG[CBC] flag bit will remain set until it is manually cleared by writing to the TZCLR[CBC] bit. If the cycle-by-cycle trip event is still present when the TZFLG[CBC] bit is cleared, then it will again be immediately set.

- **One-Shot (OSHT):**

When a one-shot trip event occurs, the action specified in the TZCTL[TZA] and TZCTL[TZB] bits is carried out immediately on the EPWMxA and/or EPWMxB output. [Table 19-19](#) lists the possible actions. In addition, the one-shot trip event flag (TZFLG[OST]) is set and a EPWMx_TZINT interrupt is generated if it is enabled in the TZEINT register and VIM peripheral. The one-shot trip condition must be cleared manually by writing to the TZCLR[OST] bit.

If the one-shot interrupt is enabled via the TZEINT register, and DCAEVT1 or DCBEVT1 are selected as OSHT trip sources via the TZSEL register, it is not necessary to also enable the DCAEVT1 or DCBEVT1 interrupts in the TZEINT register, as the DC events trigger interrupts through the OSHT mechanism.

- **Digital Compare Events (DCAEVT1/2 and DCBEVT1/2):**

A digital compare DCAEVT1/2 or DCBEVT1/2 event is generated based on a combination of the DCAH/DCAL and DCBH/DCBL signals as selected by the TZDCSEL register. The signals which source the DCAH/DCAL and DCBH/DCBL signals are selected via the DCTRIPSEL register and can be either trip zone input pins. For more information on the digital compare submodule signals, see [Section 19.2.9](#).

When a digital compare event occurs, the action specified in the TZCTL[DCAEVT1/2] and TZCTL[DCBEVT1/2] bits is carried out immediately on the EPWMxA and/or EPWMxB output. [Table 19-19](#) lists the possible actions. In addition, the relevant DC trip event flag (TZFLG[DCAEVT1/2] / TZFLG[DCBEVT1/2]) is set and a EPWMx_TZINT interrupt is generated if it is enabled in the TZEINT register and VIM peripheral.

The specified condition on the pins is automatically cleared when the DC trip event is no longer present. The TZFLG[DCAEVT1/2] or TZFLG[DCBEVT1/2] flag bit will remain set until it is manually cleared by writing to the TZCLR[DCAEVT1/2] or TZCLR[DCBEVT1/2] bit. If the DC trip event is still present when the TZFLG[DCAEVT1/2] or TZFLG[DCBEVT1/2] flag is cleared, then it will again be immediately set.

The action taken when a trip event occurs can be configured individually for each of the ePWM output pins by way of the TZCTL register bit fields. One of four possible actions, shown in [Table 19-19](#), can be taken on a trip event.

Table 19-19. Possible Actions On a Trip Event

| TZCTL Register bit-field Settings | EPWMxA and/or EPWMxB | Comment |
|-----------------------------------|----------------------|---|
| 0,0 | High-Impedance | Tripped |
| 0,1 | Force to High State | Tripped |
| 1,0 | Force to Low State | Tripped |
| 1,1 | No Change | Do Nothing. No change is made to the output. |

Example 19-7. Trip-Zone Configurations

Scenario A:

A one-shot trip event on $\overline{TZ1}$ pulls both EPWM1A, EPWM1B low and also forces EPWM2A and EPWM2B high.

- Configure the ePWM1 registers as follows:
 - TZSEL[OSHT1] = 1: enables $\overline{TZ1}$ as a one-shot event source for ePWM1
 - TZCTL[TZA] = 2: EPWM1A will be forced low on a trip event.
 - TZCTL[TZB] = 2: EPWM1B will be forced low on a trip event.
- Configure the ePWM2 registers as follows:
 - TZSEL[OSHT1] = 1: enables $\overline{TZ1}$ as a one-shot event source for ePWM2
 - TZCTL[TZA] = 1: EPWM2A will be forced high on a trip event.
 - TZCTL[TZB] = 1: EPWM2B will be forced high on a trip event.

Scenario B:

A cycle-by-cycle event on $\overline{TZ5}$ pulls both EPWM1A, EPWM1B low.

A one-shot event on $\overline{TZ1}$ or $\overline{TZ6}$ puts EPWM2A into a high impedance state.

- Configure the ePWM1 registers as follows:
 - TZSEL[CBC5] = 1: enables $\overline{TZ5}$ as a one-shot event source for ePWM1
 - TZCTL[TZA] = 2: EPWM1A will be forced low on a trip event.
 - TZCTL[TZB] = 2: EPWM1B will be forced low on a trip event.
- Configure the ePWM2 registers as follows:
 - TZSEL[OSHT1] = 1: enables $\overline{TZ1}$ as a one-shot event source for ePWM2
 - TZSEL[OSHT6] = 1: enables $\overline{TZ6}$ as a one-shot event source for ePWM2
 - TZCTL[TZA] = 0: EPWM2A will be put into a high-impedance state on a trip event.
 - TZCTL[TZB] = 3: EPWM2B will ignore the trip event.

19.2.7.4 Generating Trip Event Interrupts

Figure 19-36 and Figure 19-37 illustrate the trip-zone submodule control and interrupt logic, respectively. DCAEVT1/2 and DCBEVT1/2 signals are described in further detail in Section 19.2.9.

Figure 19-36. Trip-Zone Submodule Mode Control Logic

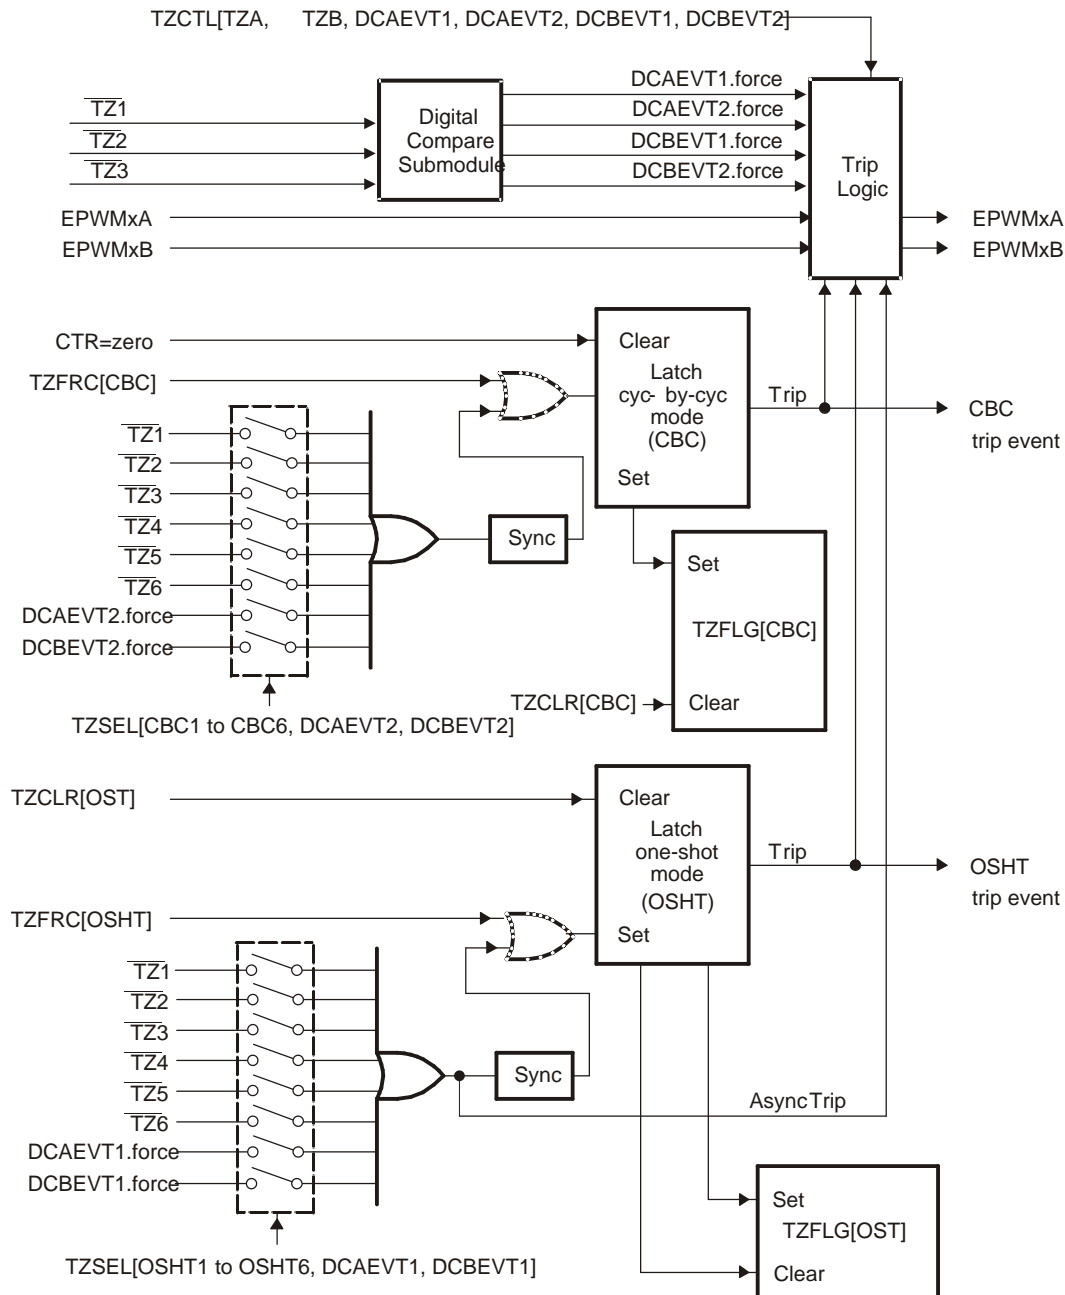

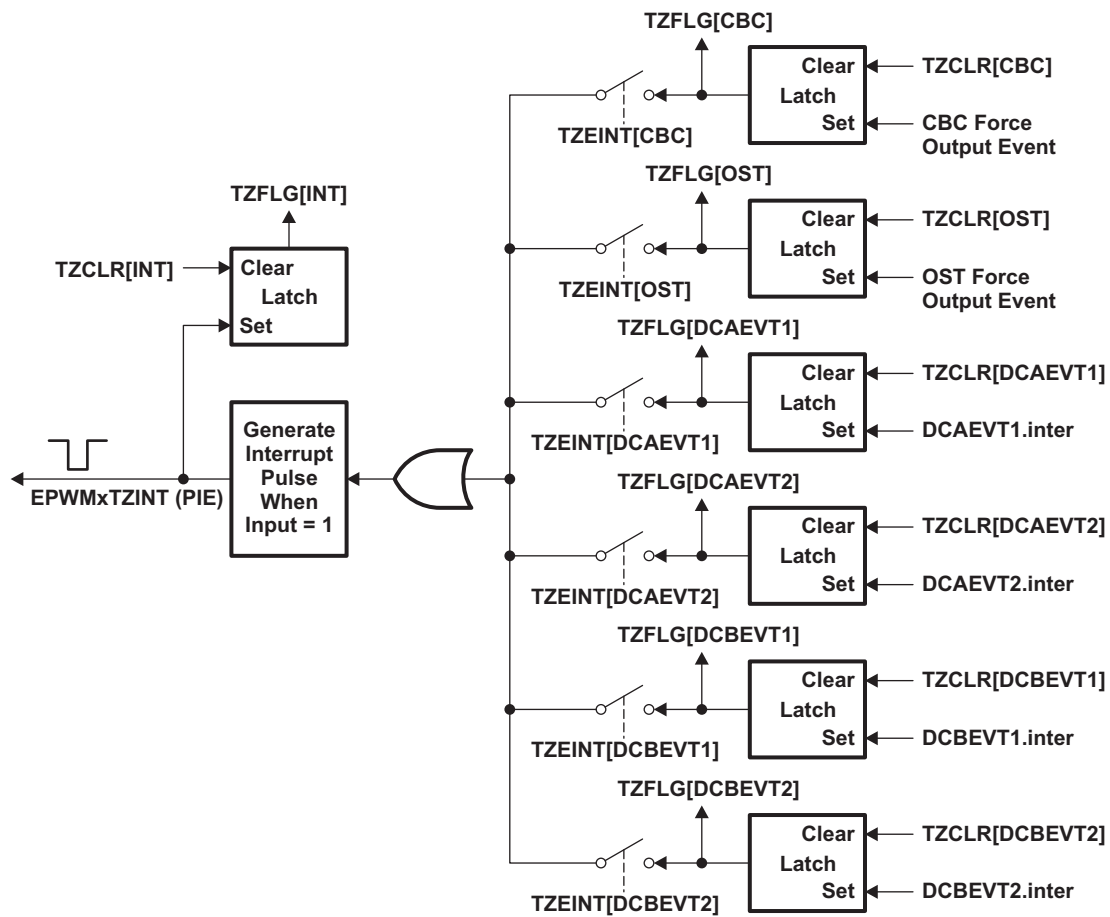

Figure 19-37. Trip-Zone Submodule Interrupt Logic

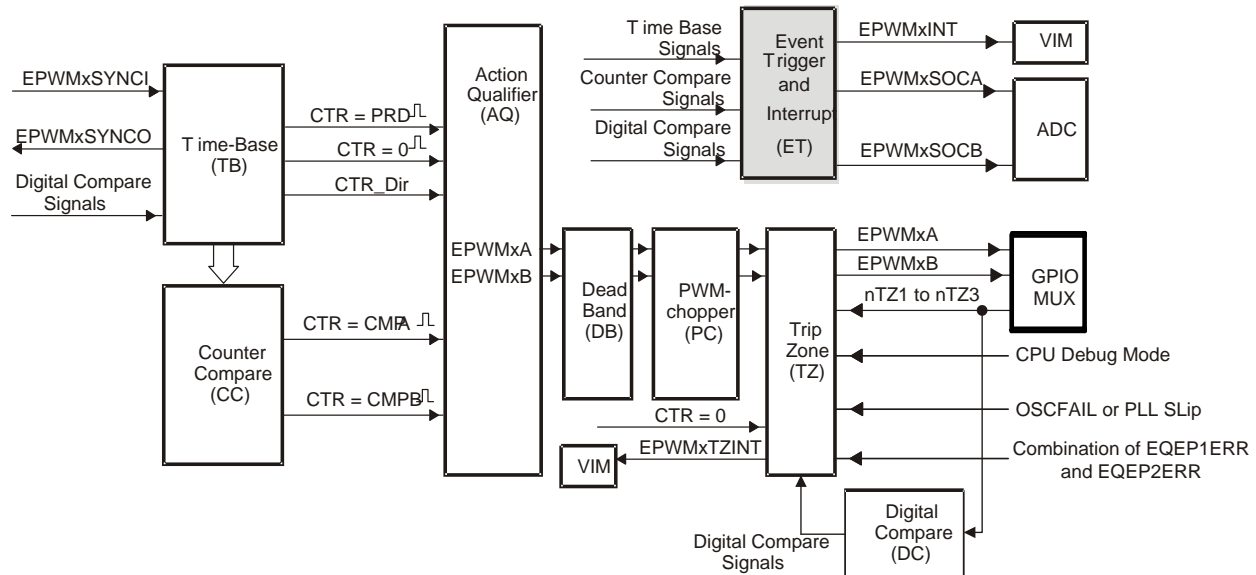

19.2.8 Event-Trigger (ET) Submodule

The key functions of the event-trigger submodule are:

- Receives event inputs generated by the time-base, counter-compare and digital-compare submodules
- Uses the time-base direction information for up/down event qualification
- Uses prescaling logic to issue interrupt requests and ADC start of conversion at:
 - Every event
 - Every second event
 - Every third event
- Provides full visibility of event generation via event counters and flags
- Allows software forcing of Interrupts and ADC start of conversion

The event-trigger submodule manages the events generated by the time-base submodule, the counter-compare submodule, and the digital-compare submodule to generate an interrupt to the CPU and/or a start of conversion pulse to the ADC when a selected event occurs. [Figure 19-38](#) illustrates where the event-trigger submodule fits within the ePWM system.

Figure 19-38. Event-Trigger Submodule

19.2.8.1 Operational Overview of the Event-Trigger Submodule

The following sections describe the event-trigger submodule's operational highlights.

Each ePWM module has one interrupt request line connected to the VIM and two start of conversion signals connected to the ADC module. As shown in [Figure 19-39](#), the EPWMxSOCA and EPWMxSOCA_B signals are combined to generate four special signals that can be used to trigger an ADC start of conversion, and hence multiple modules can initiate an ADC start of conversion via the ADC trigger inputs.

The event-trigger submodule monitors various event conditions (the left side inputs to event-trigger submodule shown in [Figure 19-40](#)) and can be configured to prescale these events before issuing an Interrupt request or an ADC start of conversion. The event-trigger prescaling logic can issue Interrupt requests and ADC start of conversion at:

- Every event
- Every second event
- Every third event

Figure 19-39. Event-Trigger Submodule Inter-Connectivity of ADC Start of Conversion

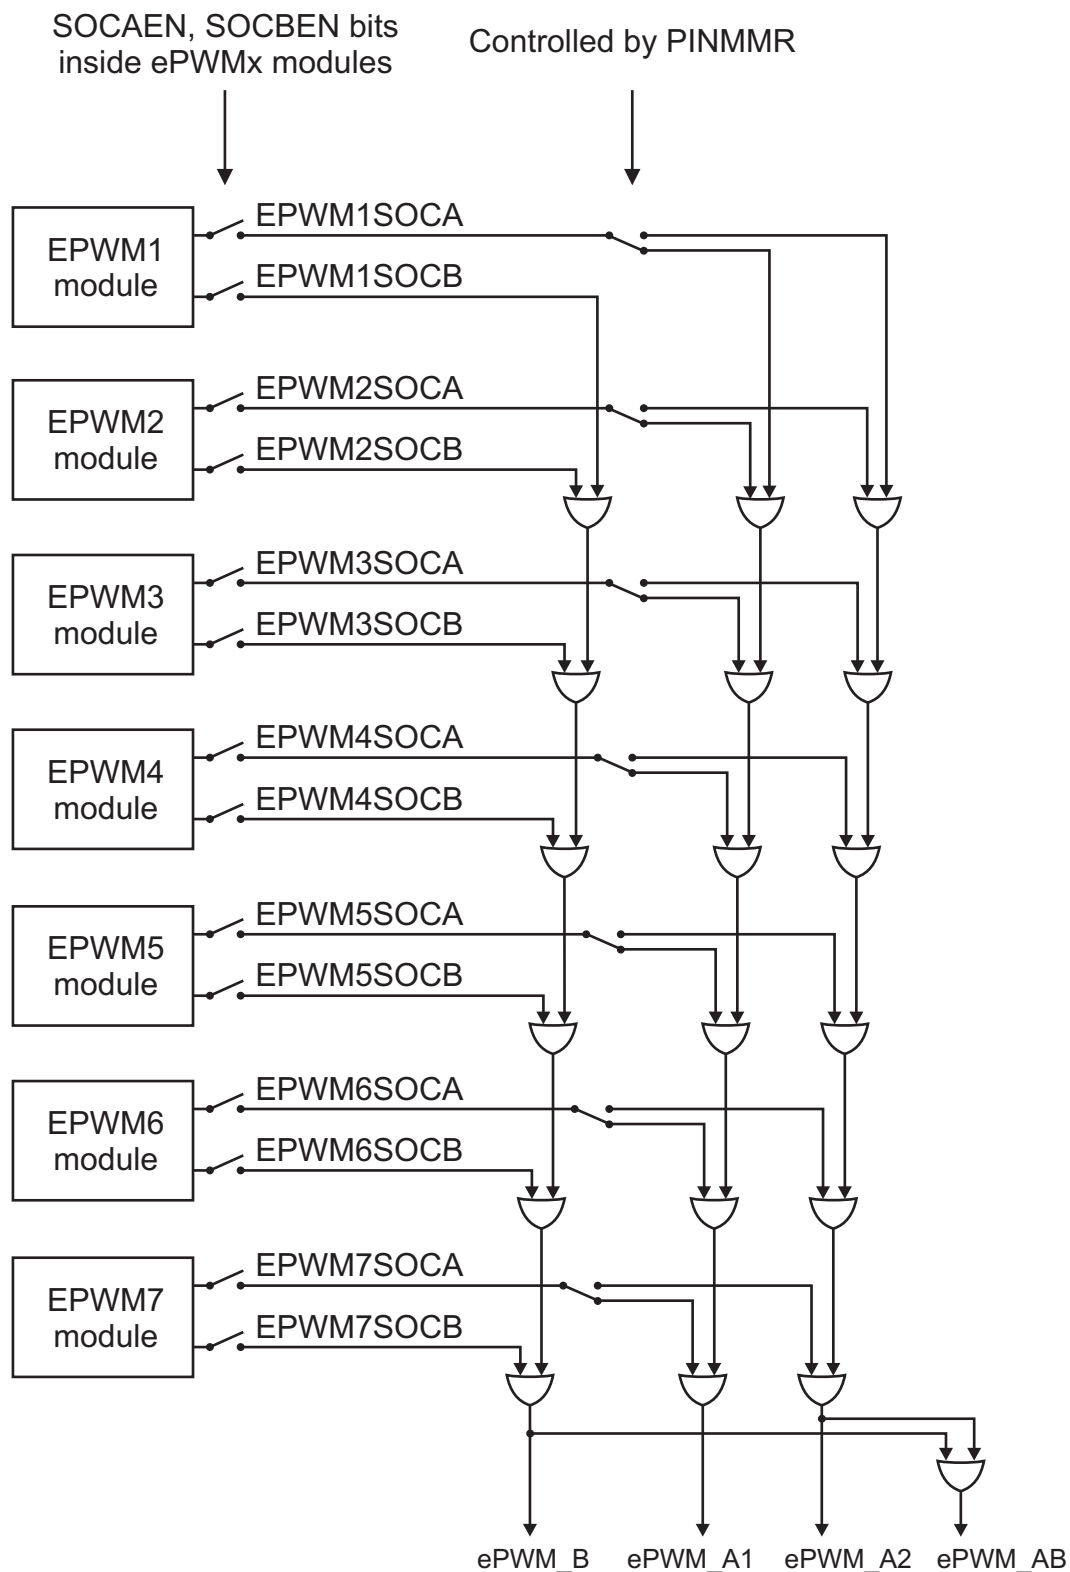

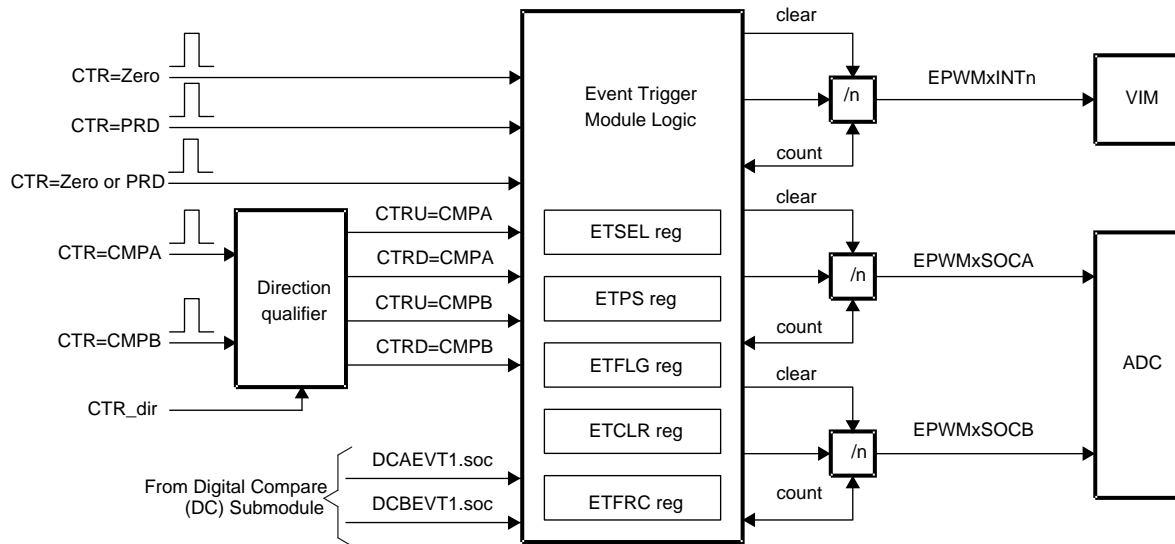

Figure 19-40. Event-Trigger Submodule Showing Event Inputs and Prescaled Outputs

The key registers used to configure the event-trigger submodule are shown in [Table 19-20](#).

Table 19-20. Event-Trigger Submodule Registers

| Register Name | Address Offset | Shadowed | Description |
|---------------|----------------|----------|----------------------------------|
| ETSEL | 0x0030 | No | Event-trigger Selection Register |
| ETPS | 0x0036 | No | Event-trigger Prescale Register |
| ETFLG | 0x0034 | No | Event-trigger Flag Register |
| ETCLR | 0x003A | No | Event-trigger Clear Register |
| ETFRC | 0x0038 | No | Event-trigger Force Register |

- ETSEL—This selects which of the possible events will trigger an interrupt or start an ADC conversion
- ETPS—This programs the event prescaling options mentioned above.
- ETFLG—These are flag bits indicating status of the selected and prescaled events.
- ETCLR—These bits allow you to clear the flag bits in the ETFLG register via software.
- ETFRC—These bits allow software forcing of an event. Useful for debugging or s/w intervention.

A more detailed look at how the various register bits interact with the Interrupt and ADC start of conversion logic are shown in [Figure 19-41](#), [Figure 19-42](#), and [Figure 19-43](#).

[Figure 19-41](#) shows the event-trigger's interrupt generation logic. The interrupt-period (ETPS[INTPRD]) bits specify the number of events required to cause an interrupt pulse to be generated. The choices available are:

- Do not generate an interrupt.
- Generate an interrupt on every event
- Generate an interrupt on every second event
- Generate an interrupt on every third event

Which event can cause an interrupt is configured by the interrupt selection (ETSEL[INTSEL]) bits. The event can be one of the following:

- Time-base counter equal to zero (TBCTR = 0x0000).
- Time-base counter equal to period (TBCTR = TBPRD).
- Time-base counter equal to zero or period (TBCTR = 0x0000 || TBCTR = TBPRD)

- Time-base counter equal to the compare A register (CMPA) when the timer is incrementing.
- Time-base counter equal to the compare A register (CMPA) when the timer is decrementing.
- Time-base counter equal to the compare B register (CMPB) when the timer is incrementing.
- Time-base counter equal to the compare B register (CMPB) when the timer is decrementing.

The number of events that have occurred can be read from the interrupt event counter (ETPS[INTCNT]) register bits. That is, when the specified event occurs the ETPS[INTCNT] bits are incremented until they reach the value specified by ETPS[INTPRD]. When ETPS[INTCNT] = ETPS[INTPRD] the counter stops counting and its output is set. The counter is only cleared when an interrupt is sent to the VIM.

When ETPS[INTCNT] reaches ETPS[INTPRD] the following behaviors will occur:

- If interrupts are enabled, ETSEL[INTEN] = 1 and the interrupt flag is clear, ETFLG[INT] = 0, then an interrupt pulse is generated and the interrupt flag is set, ETFLG[INT] = 1, and the event counter is cleared ETPS[INTCNT] = 0. The counter will begin counting events again.
- If interrupts are disabled, ETSEL[INTEN] = 0, or the interrupt flag is set, ETFLG[INT] = 1, the counter stops counting events when it reaches the period value ETPS[INTCNT] = ETPS[INTPRD].
- If interrupts are enabled, but the interrupt flag is already set, then the counter will hold its output high until the ENTFLG[INT] flag is cleared. This allows for one interrupt to be pending while one is serviced.

Writing to the INTPRD bits will automatically clear the counter INTCNT = 0 and the counter output will be reset (so no interrupts are generated). Writing a 1 to the ETFRC[INT] bit will increment the event counter INTCNT. The counter will behave as described above when INTCNT = INTPRD. When INTPRD = 0, the counter is disabled and hence no events will be detected and the ETFRC[INT] bit is also ignored.

The above definition means that you can generate an interrupt on every event, on every second event, or on every third event. An interrupt cannot be generated on every fourth or more events.

Figure 19-41. Event-Trigger Interrupt Generator

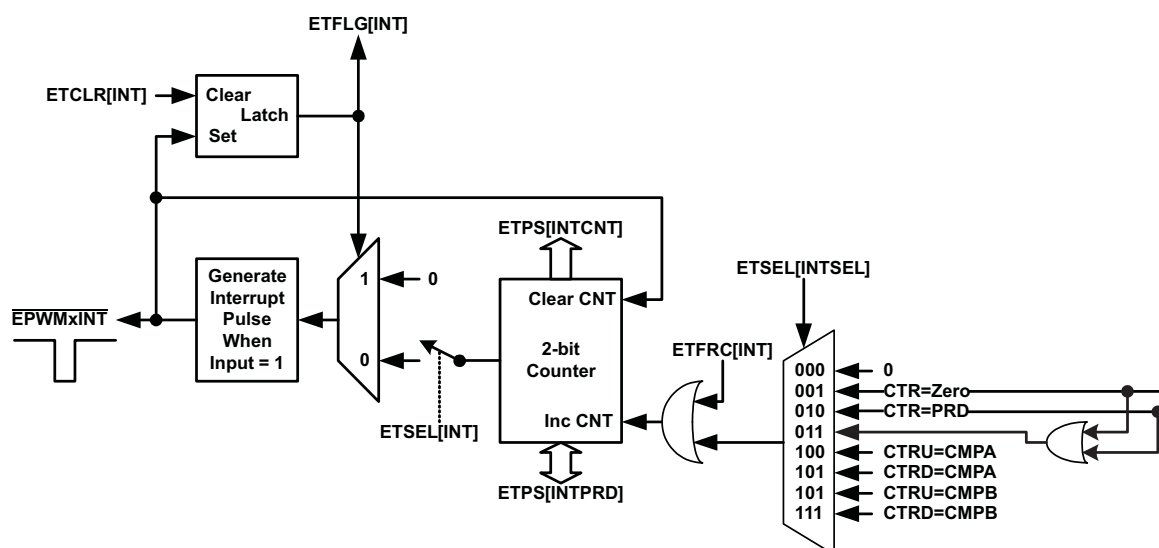

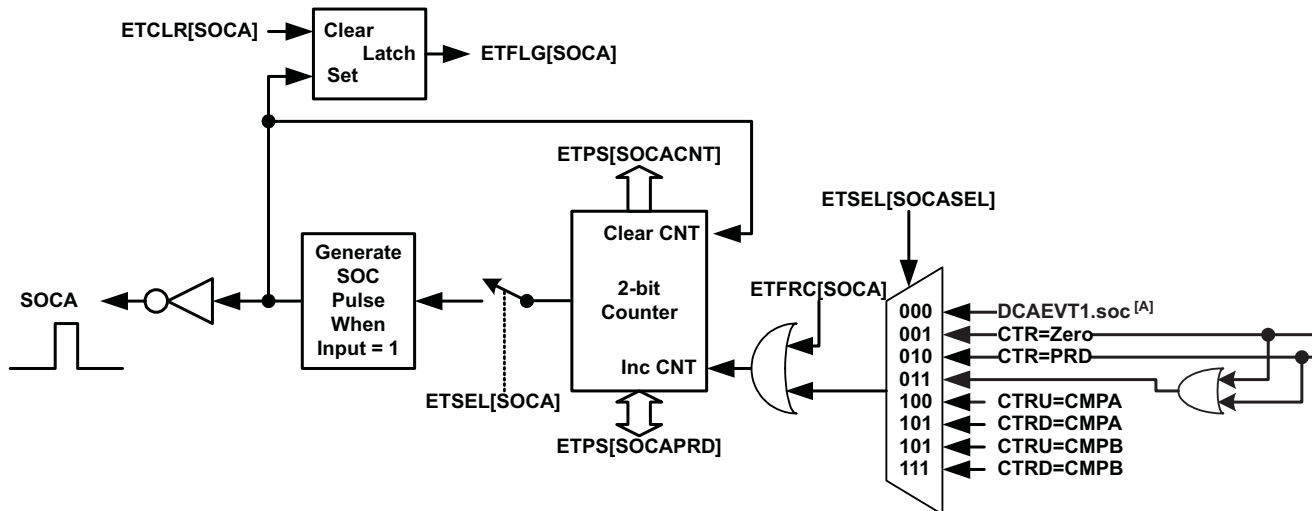

Figure 19-42 shows the operation of the event-trigger's start-of-conversion-A (SOCA) pulse generator. The ETPS[SOCACNT] counter and ETPS[SOCAPRD] period values behave similarly to the interrupt generator except that the pulses are continuously generated. That is, the pulse flag ETFLG[SOCA] is latched when a pulse is generated, but it does not stop further pulse generation. The enable/disable bit ETSEL[SOCAEN] stops pulse generation, but input events can still be counted until the period value is reached as with the interrupt generation logic. The event that will trigger an SOCA and SOCB pulse can be configured separately in the ETSEL[SOCASEL] and ETSEL[SOCBSEL] bits. The possible events are the same events that can be specified for the interrupt generation logic with the addition of the DCAEVT1.soc and DCBEVT1.soc event signals from the digital compare (DC) submodule.

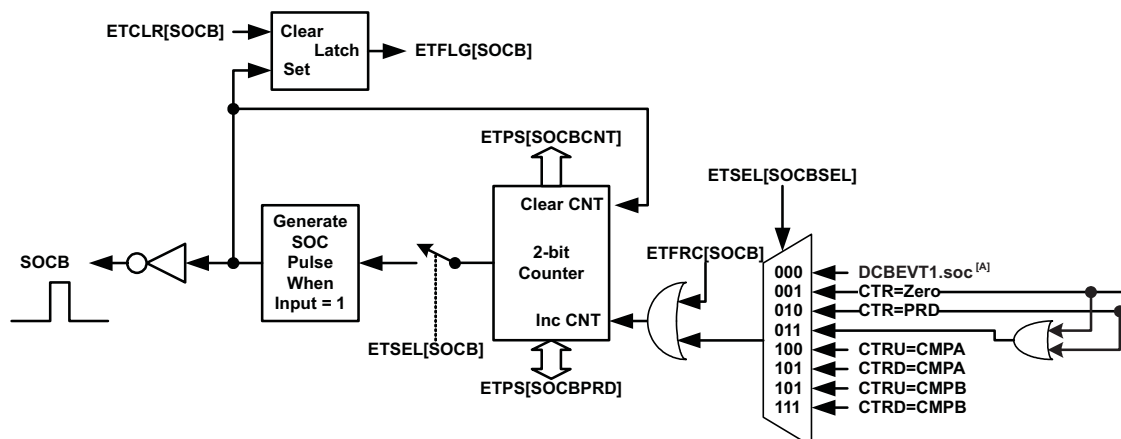

Figure 19-42. Event-Trigger SOCA Pulse Generator

A The DCAEVT1.soc signals are signals generated by the Digital compare (DC) submodule described later in Section 19.2.9.

Figure 19-43 shows the operation of the event-trigger's start-of-conversion-B (SOCB) pulse generator. The event-trigger's SOCB pulse generator operates the same way as the SOCA.

Figure 19-43. Event-Trigger SOCB Pulse Generator

A The DCBEVT1.soc signals are signals generated by the Digital compare (DC) submodule described later in Section 19.2.9.

19.2.9 Digital Compare (DC) Submodule

Figure 19-44 illustrates where the digital compare (DC) submodule signals interface to other submodules in the ePWM system.

The digital compare (DC) submodule compares signals external to the ePWM module to directly generate PWM events/actions that then feed to the event-trigger, trip-zone, and time-base submodules. Additionally, blanking window functionality is supported to filter noise or unwanted pulses from the DC event signals.

Figure 19-44. Digital-Compare Submodule High-Level Block Diagram

19.2.9.1 Purpose of the Digital Compare Submodule

The key functions of the digital compare submodule are:

- TZ1, TZ2, and TZ3 inputs generate Digital Compare A High/Low (DCAH, DCAL) and Digital Compare B High/Low (DCBH, DCBL) signals.
- DCAH/L and DCBH/L signals trigger events which can then either be filtered or fed directly to the trip-zone, event-trigger, and time-base submodules to:
 - generate a trip zone interrupt
 - generate an ADC start of conversion
 - force an event
 - generate a synchronization event for synchronizing the ePWM module TBCTR.
- Event filtering (blanking window logic) can optionally blank the input signal to remove noise.

19.2.9.2 Controlling and Monitoring the Digital Compare Submodule

The digital compare submodule operation is controlled and monitored through the following registers:

Table 19-21. Digital Compare Submodule Registers

| Register Name | Address Offset | Shadowed | Description |
|---------------------------------------|----------------|----------|--|
| TZDCSEL ⁽¹⁾ ⁽²⁾ | 0x0024 | No | Trip Zone Digital Compare Select Register |
| DCTRIPSEL ⁽¹⁾ | 0x0062 | No | Digital Compare Trip Select Register |
| DCACTL ⁽¹⁾ | 0x0060 | No | Digital Compare A Control Register |
| DCBCTL ⁽¹⁾ | 0x0066 | No | Digital Compare B Control Register |
| DCFCTL ⁽¹⁾ | 0x0064 | No | Digital Compare Filter Control Register |
| DCCAPCTL ⁽¹⁾ | 0x006A | No | Digital Compare Capture Control Register |
| DCFOFFSET | 0x0068 | Writes | Digital Compare Filter Offset Register |
| DCFOFFSETCNT | 0x006E | No | Digital Compare Filter Offset Counter Register |
| DCFWINDOW | 0x006C | No | Digital Compare Filter Window Register |
| DCFWINDOWCNT | 0x0072 | No | Digital Compare Filter Window Counter Register |
| DCCAP | 0x0070 | Yes | Digital Compare Counter Capture Register |

⁽¹⁾ These registers are writable only in privileged mode.

⁽²⁾ The TZDCSEL register is part of the trip-zone submodule but is mentioned again here because of its functional significance to the digital compare submodule.

19.2.9.3 Operation Highlights of the Digital Compare Submodule

The following sections describe the operational highlights and configuration options for the digital compare submodule.

19.2.9.3.1 Digital Compare Events

As illustrated in [Figure 19-44](#), trip zone inputs ($\overline{TZ1}$, $\overline{TZ2}$, and $\overline{TZ3}$) can be selected via the DCTRIPSEL bits to generate the Digital Compare A High and Low (DCAH/L) and Digital Compare B High and Low (DCBH/L) signals. Then, the configuration of the TZDCSEL register qualifies the actions on the selected DCAH/L and DCBH/L signals, which generate the DCAEVT1/2 and DCBEVT1/2 events (Event Qualification A and B).

NOTE: The \overline{TZn} signals, when used as a DCEVT tripping functions, are treated as a normal input signal and can be defined to be active high or active low inputs. EPWM outputs are asynchronously tripped when either the \overline{TZn} , DCAEVTx.force, or DCBEVTx.force signals are active. For the condition to remain latched, a minimum of $3 \times \text{TBCLK}$ sync pulse width is required. If pulse width is $< 3 \times \text{TBCLK}$ sync pulse width, the trip condition may or may not get latched by CBC or OST latches.

The DCAEVT1/2 and DCBEVT1/2 events can then be filtered to provide a filtered version of the event signals (DCEVTFILT) or the filtering can be bypassed. Filtering is discussed further in [Section 19.2.9.3.2](#). Either the DCAEVT1/2 and DCBEVT1/2 event signals or the filtered DCEVTFILT event signals can generate a force to the trip zone module, a TZ interrupt, an ADC SOC, or a PWM sync signal.

- **force signal:**

DCAEVT1/2.force signals force trip zone conditions which either directly influence the output on the EPWMxA pin (via TZCTL[DCAEVT1 or DCAEVT2] configurations) or, if the DCAEVT1/2 signals are selected as one-shot or cycle-by-cycle trip sources (via the TZSEL register), the DCAEVT1/2.force signals can effect the trip action via the TZCTL[TZA] configuration. The DCBEVT1/2.force signals behaves similarly, but affect the EPWMxB output pin instead of the EPWMxA output pin.

The priority of conflicting actions on the TZCTL register is as follows (highest priority overrides lower priority):

Output EPWMxA: TZA (highest) -> DCAEVT1 -> DCAEVT2 (lowest)

Output EPWMxB: TZB (highest) -> DCBEVT1 -> DCBEVT2 (lowest)

- **interrupt signal:**

DCAEVT1/2.interrupt signals generate trip zone interrupts to the VIM. To enable the interrupt, the user must set the DCAEVT1, DCAEVT2, DCBEVT1, or DCBEVT2 bits in the TZEINT register. Once one of these events occurs, an EPWMxTZINT interrupt is triggered, and the corresponding bit in the TZCLR register must be set in order to clear the interrupt.

- **soc signal:**

The DCAEVT1.soc signal interfaces with the event-trigger submodule and can be selected as an event which generates an ADC start-of-conversion-A (SOCA) pulse via the ETSEL[SOCASEL] bit. Likewise, the DCBEVT1.soc signal can be selected as an event which generates an ADC start-of-conversion-B (SOCB) pulse via the ETSEL[SOCBSEL] bit.

- **sync signal:**

The DCAEVT1.sync and DCBEVT1.sync events are ORed with the EPWMxSYNCl input signal and the TBCTL[SWFSYNC] signal to generate a synchronization pulse to the time-base counter.

[Figure 19-45](#) and [Figure 19-46](#) show how the DCAEVT1, DCAEVT2, or DCEVTFILT signals are processed to generate the digital compare A event force, interrupt, soc and sync signals.

Figure 19-45. DCAEVT1 Event Triggering

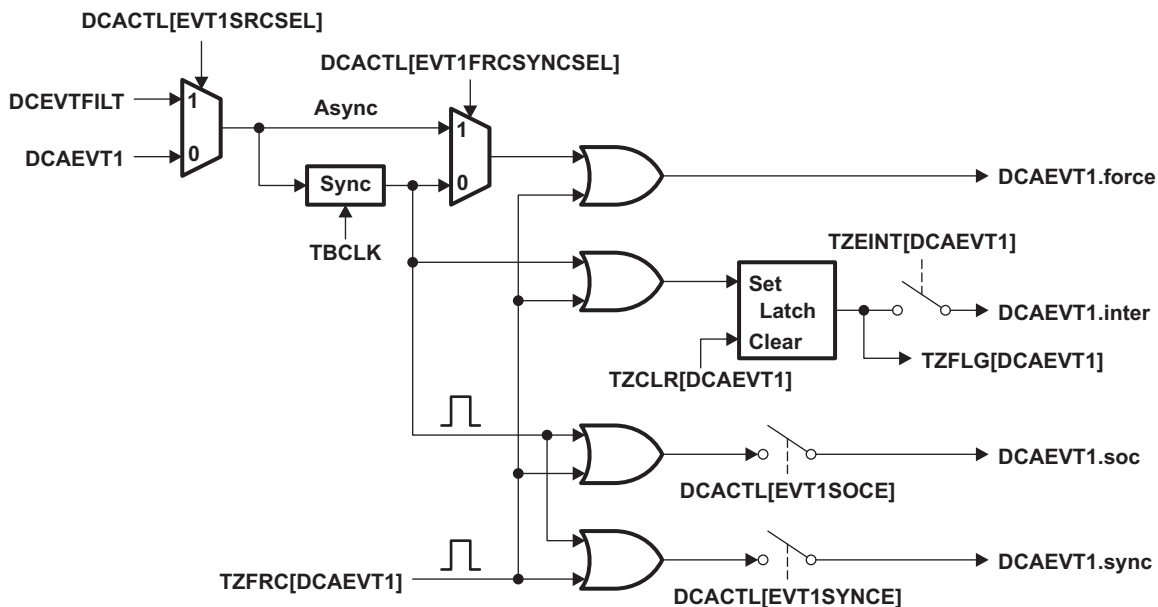

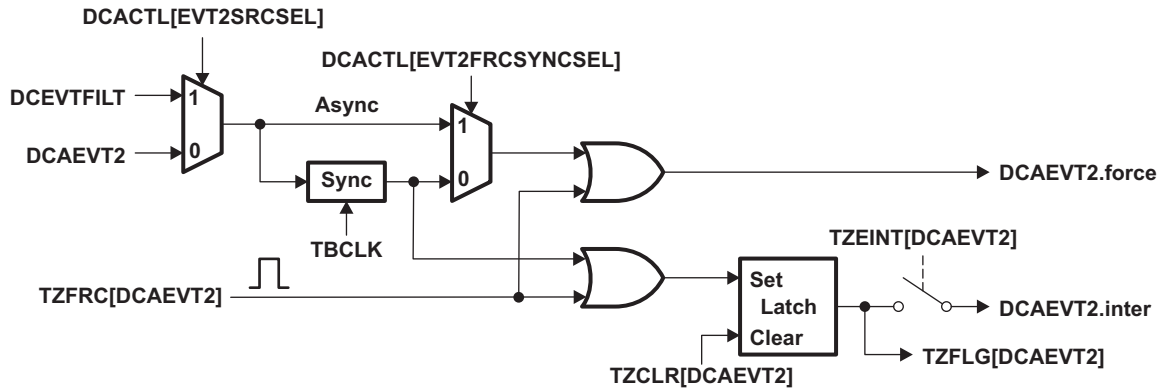

Figure 19-46. DCAEV2 Event Triggering

Figure 19-47 and Figure 19-48 show how the DCBEVT1, DCBEVT2, or DCEVTFILT signals are processed to generate the digital compare B event force, interrupt, soc, and sync signals.

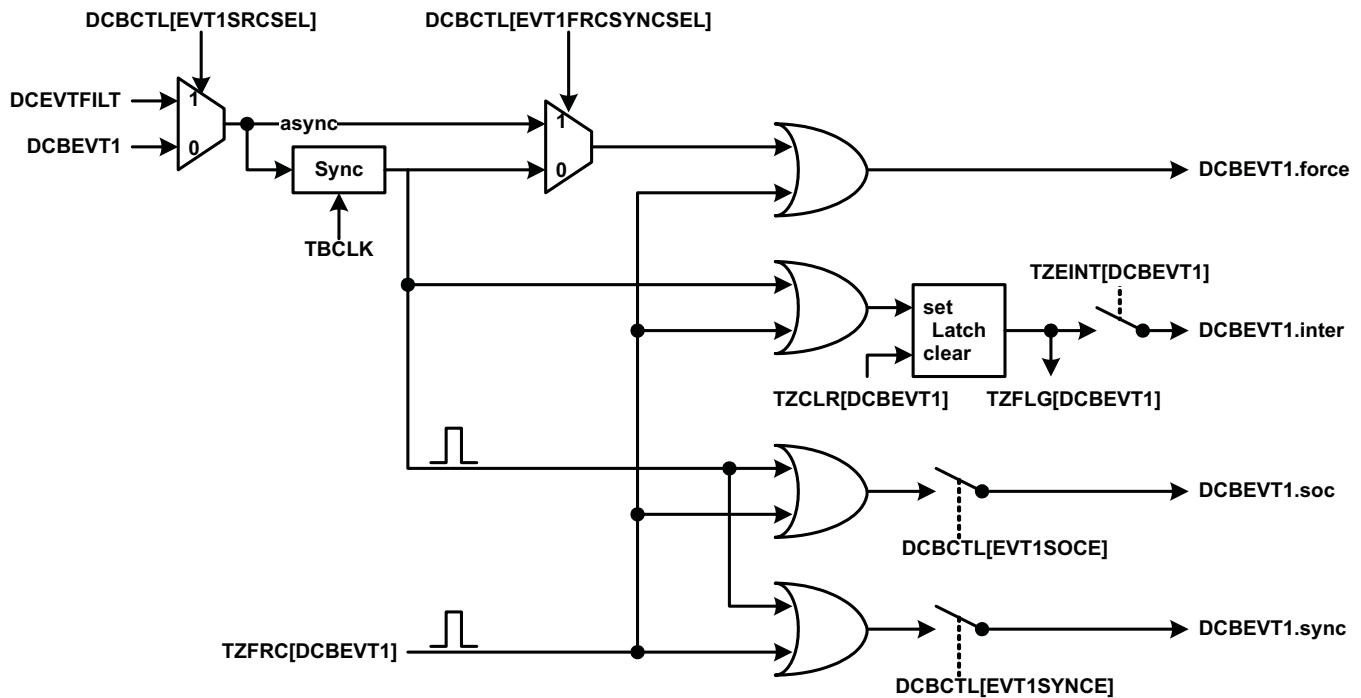

Figure 19-47. DCBEVT1 Event Triggering

Figure 19-48. DCBEVT2 Event Triggering

19.2.9.3.2 Event Filtering

The DCAEVT1/2 and DCBEVT1/2 events can be filtered via event filtering logic to remove noise by optionally blanking events for a certain period of time. This is useful for cases where the analog comparator outputs may be selected to trigger DCAEVT1/2 and DCBEVT1/2 events, and the blanking logic is used to filter out potential noise on the signal prior to tripping the PWM outputs or generating an interrupt or ADC start-of-conversion. The event filtering can also capture the TBCTR value of the trip event. Figure 19-49 shows the details of the event filtering logic.

If the blanking logic is enabled, one of the digital compare events – DCAEVT1, DCAEVT2, DCBEVT1, DCBEVT2 – is selected for filtering. The blanking window, which filters out all event occurrences on the signal while it is active, will be aligned to either a CTR = PRD pulse or a CTR = 0 pulse (configured by the DCFCTL[PULSESEL] bits). An offset value in TBCLK counts is programmed into the DCFOFFSET register, which determines at what point after the CTR = PRD or CTR = 0 pulse the blanking window starts. The duration of the blanking window, in number of TBCLK counts after the offset counter expires, is written to the DCFWINDOW register by the application. During the blanking window, all events are ignored. Before and after the blanking window ends, events can generate soc, sync, interrupt, and force signals as before.

Figure 19-50 illustrates several timing conditions for the offset and blanking window within an ePWM period. Notice that if the blanking window crosses the CTR = 0 or CTR = PRD boundary, the next window still starts at the same offset value after the CTR = 0 or CTR = PRD pulse.

Figure 19-49. Event Filtering

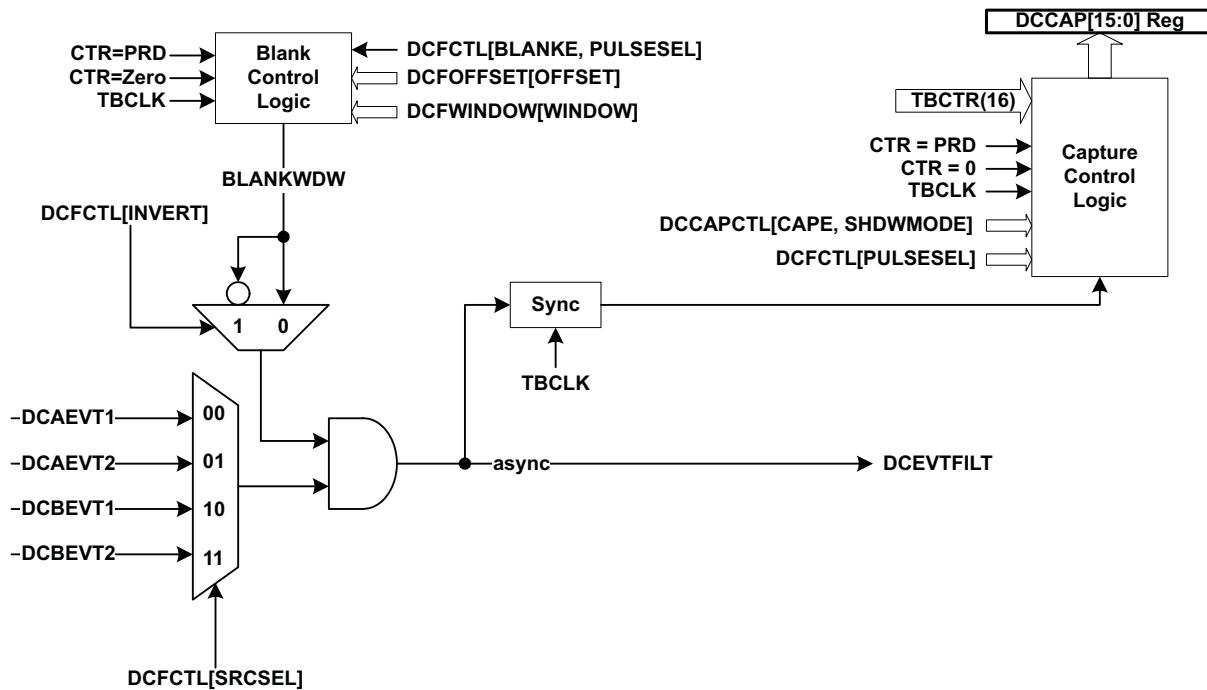

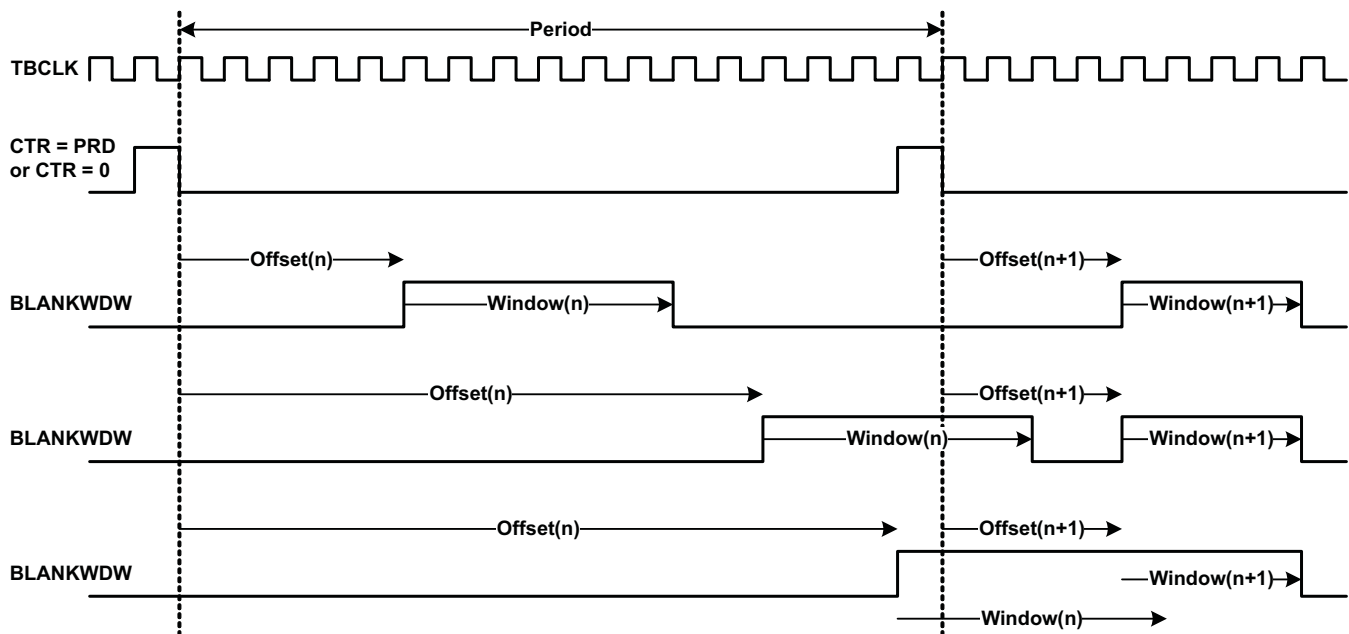

Figure 19-50. Blanking Window Timing Diagram

19.2.10 Proper Interrupt Initialization Procedure

When the ePWM peripheral clock is enabled it may be possible that interrupt flags may be set due to spurious events due to the ePWM registers not being properly initialized. The proper procedure for initializing the ePWM peripheral is as follows:

1. Disable global interrupts (CPU INTM flag)
2. Disable ePWM interrupts
3. Set TBCLKSYNC = 0
4. Initialize peripheral registers
5. Set TBCLKSYNC = 1
6. Clear any spurious ePWM flags (including interrupt flags)
7. Enable ePWM interrupts
8. Enable global interrupts

19.3 Application Examples

An ePWM module has all the local resources necessary to operate completely as a standalone module or to operate in synchronization with other identical ePWM modules.

19.3.1 Overview of Multiple Modules

Previously in this chapter, all discussions have described the operation of a single module. To facilitate the understanding of multiple modules working together in a system, the ePWM module described in reference is represented by the more simplified block diagram shown in [Figure 19-51](#). This simplified ePWM block shows only the key resources needed to explain how a multiswitch power topology is controlled with multiple ePWM modules working together.

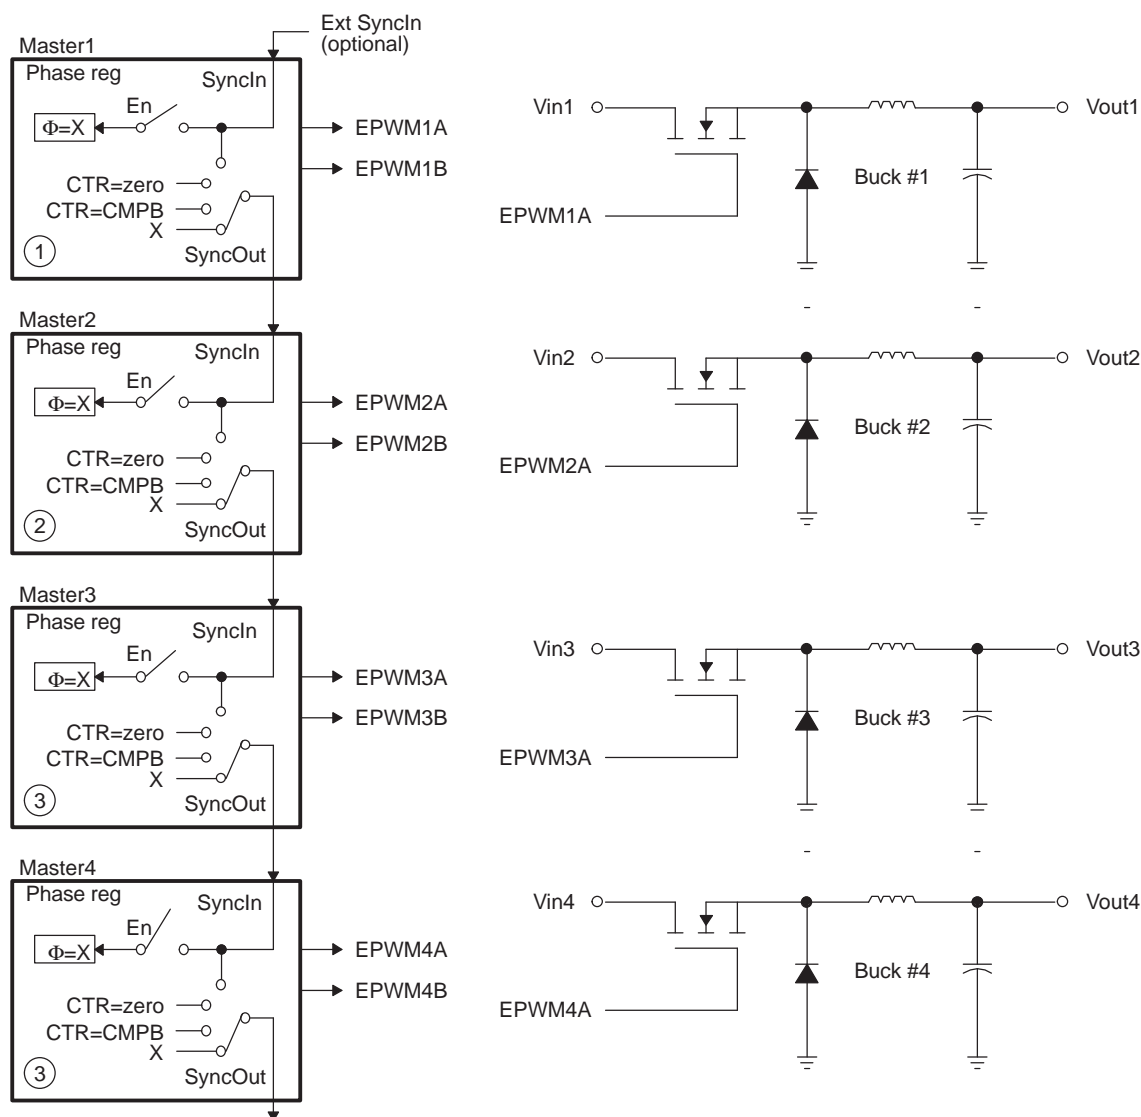

Figure 19-51. Simplified ePWM Module

19.3.3 Controlling Multiple Buck Converters With Independent Frequencies

One of the simplest power converter topologies is the buck. A single ePWM module configured as a master can control two buck stages with the same PWM frequency. If independent frequency control is required for each buck converter, then one ePWM module must be allocated for each converter stage. Figure 19-53 shows four buck stages, each running at independent frequencies. In this case, all four ePWM modules are configured as Masters and no synchronization is used. Figure 19-54 shows the waveforms generated by the setup shown in Figure 19-53; note that only three waveforms are shown, although there are four stages.

Figure 19-53. Control of Four Buck Stages. Here $F_{PWM1} \neq F_{PWM2} \neq F_{PWM3} \neq F_{PWM4}$

NOTE: $\Phi = X$ indicates value in phase register is a "don't care"

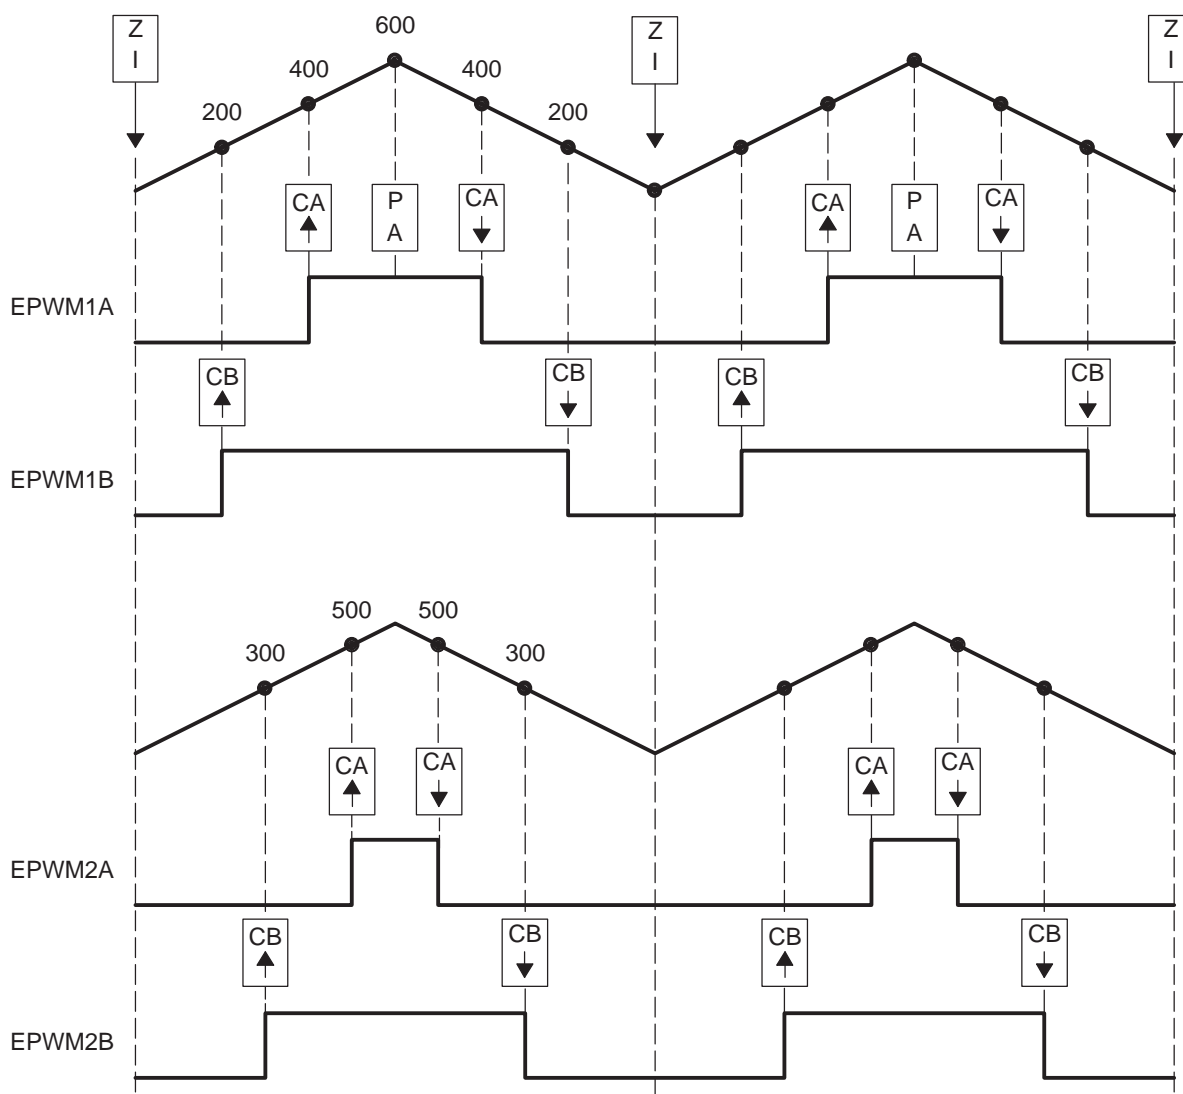

Figure 19-54. Buck Waveforms for Figure 19-53 (Note: Only three bucks shown here)

EPwm1Regs.CMPB = 200; // adjust duty for output EPWM1B
EPwm2Regs.CMPA.half.CMPA = 500; // adjust duty for output EPWM2A
EPwm2Regs.CMPB = 300; // adjust duty for output EPWM2B
```

19.3.5 Controlling Multiple Half H-Bridge (HHB) Converters

Topologies that require control of multiple switching elements can also be addressed with these same ePWM modules. It is possible to control a Half-H bridge stage with a single ePWM module. This control can be extended to multiple stages. Figure 19-57 shows control of two synchronized Half-H bridge stages where stage 2 can operate at integer multiple (N) frequencies of stage 1. Figure 19-58 shows the waveforms generated by the configuration shown in Figure 19-57.

Module 2 (slave) is configured for Sync flow-through; if required, this configuration allows for a third Half-H bridge to be controlled by PWM module 3 and also, most importantly, to remain in synchronization with master module 1.

Figure 19-57. Control of Two Half-H Bridge Stages ($F_{PWM2} = N \times F_{PWM1}$)

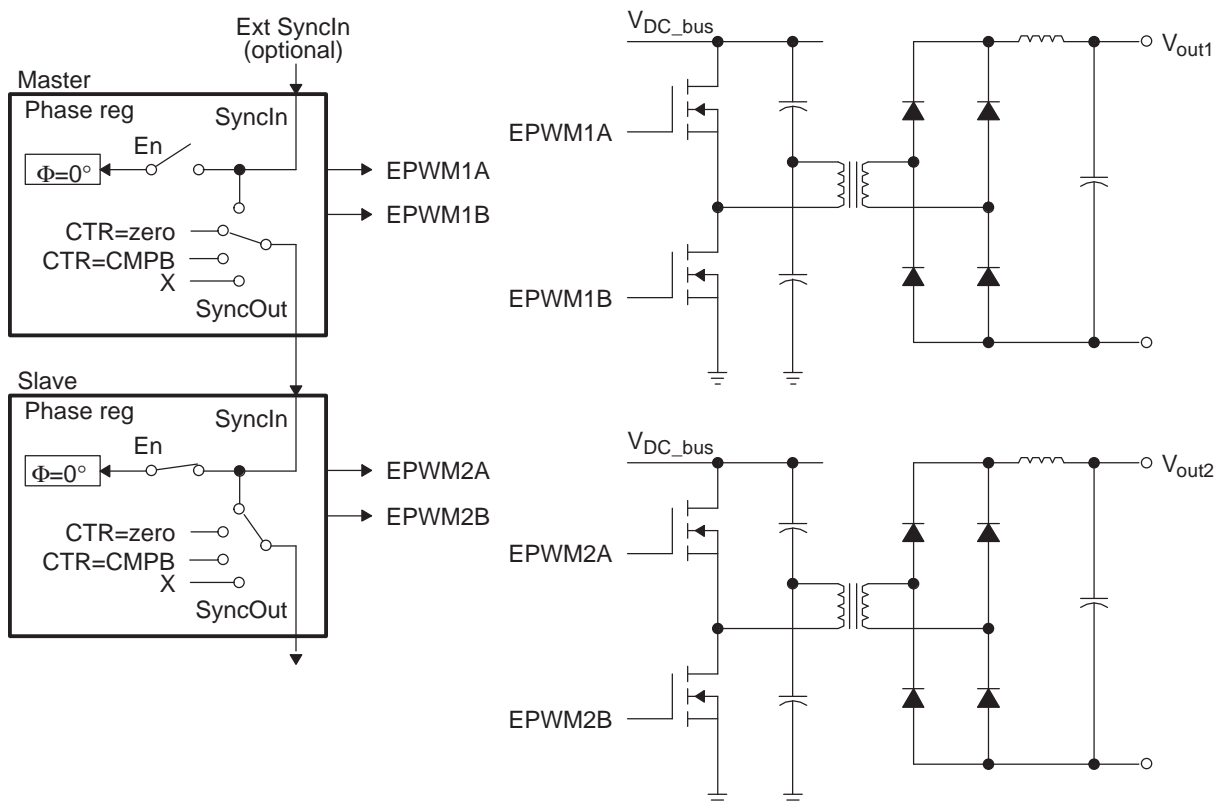

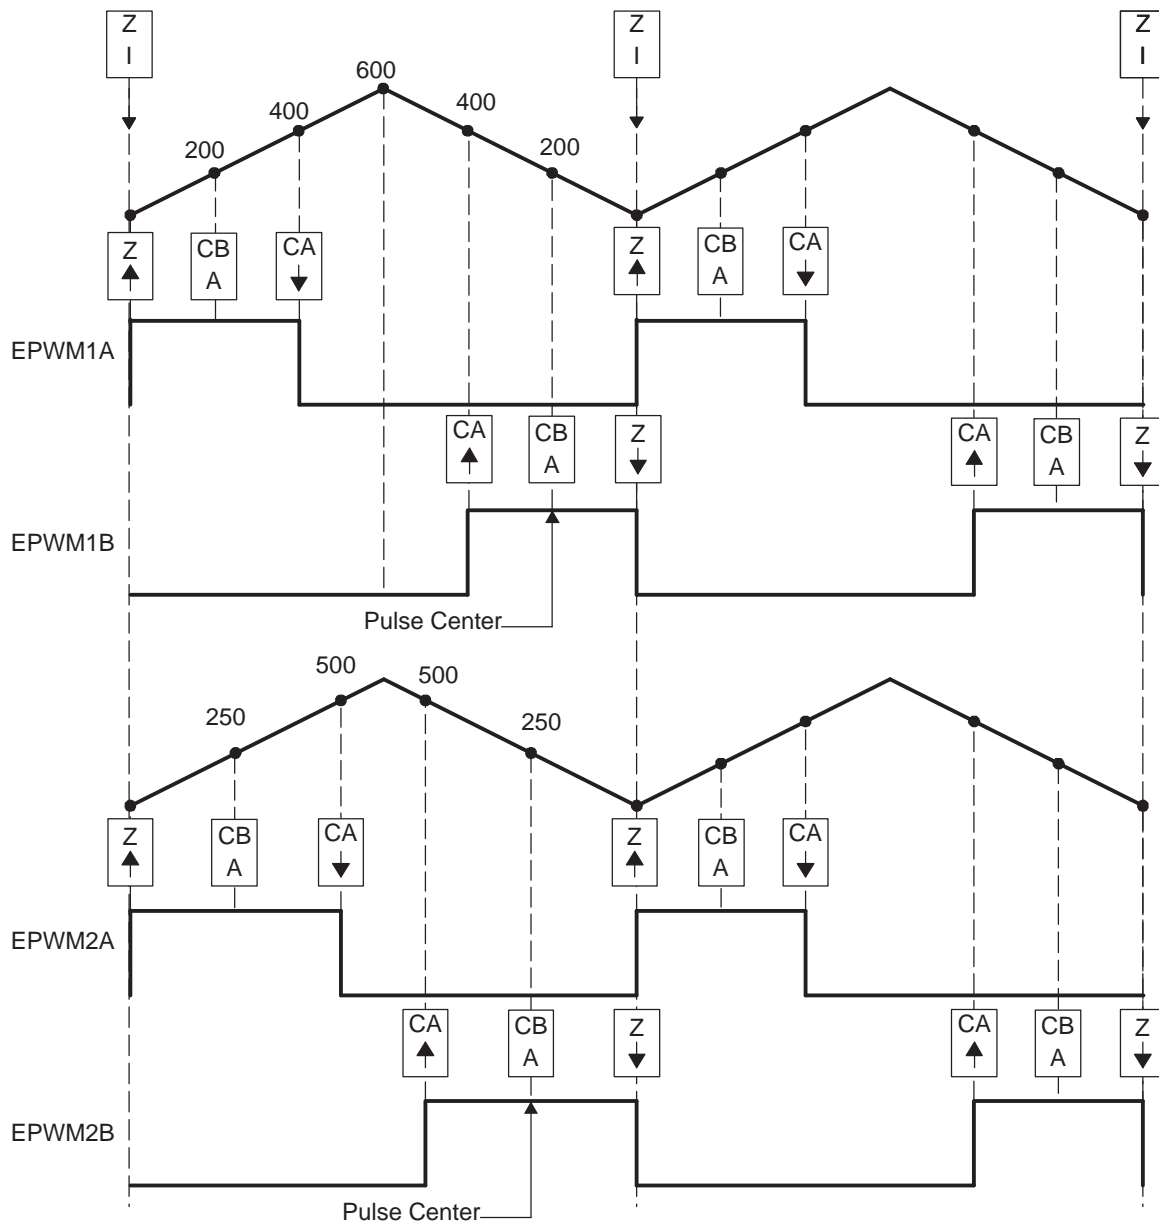

Figure 19-58. Half-H Bridge Waveforms for Figure 19-57 (Note: Here $F_{PWM2} = F_{PWM1}$)

Example 19-10. Code Snippet for Configuration in Figure 19-57

```
//=====
// Config
//=====
// Initialization Time
//=====
// EPWM Module 1 config
    EPwm1Regs.TBPRD = 600;                // Period = 1200 TBCLK counts
    EPwm1Regs.TBPHS.half.TBPHS = 0;      // Set Phase register to zero
    EPwm1Regs.TBCTL.bit.CTRMODE = TB_COUNT_UPDOWN; // Symmetrical mode
    EPwm1Regs.TBCTL.bit.PHSEN = TB_DISABLE; // Master module
    EPwm1Regs.TBCTL.bit.PRDL = TB_SHADOW;
    EPwm1Regs.TBCTL.bit.SYNCSEL = TB_CTR_ZERO; // Sync down-stream module
    EPwm1Regs.CMPCTL.bit.SHDWAMODE = CC_SHADOW;
    EPwm1Regs.CMPCTL.bit.SHDWBMODE = CC_SHADOW;
    EPwm1Regs.CMPCTL.bit.LOADAMODE = CC_CTR_ZERO; // load on CTR=Zero
    EPwm1Regs.CMPCTL.bit.LOADBMODE = CC_CTR_ZERO; // load on CTR=Zero
    EPwm1Regs.AQCTLA.bit.ZRO = AQ_SET;    // set actions for EPWM1A
    EPwm1Regs.AQCTLA.bit.CAU = AQ_CLEAR;
    EPwm1Regs.AQCTLB.bit.ZRO = AQ_CLEAR;  // set actions for EPWM1B

    EPwm1Regs.CMPA.half.CMPA = 400;      // adjust duty for output EPWM1A & EPWM1B

    EPwm1Regs.CMPB = 200;                // adjust point-in-time for ADCSOC trigger
    EPwm2Regs.CMPA.half.CMPA = 500;      // adjust duty for output EPWM2A & EPWM2B
    EPwm2Regs.CMPB = 250;                // adjust point-in-time for ADCSOC trigger
```

19.3.6 Controlling Dual 3-Phase Inverters for Motors (ACI and PMSM)

The idea of multiple modules controlling a single power stage can be extended to the 3-phase Inverter case. In such a case, six switching elements can be controlled using three PWM modules, one for each leg of the inverter. Each leg must switch at the same frequency and all legs must be synchronized. A master + two slaves configuration can easily address this requirement. [Figure 19-59](#) shows how six PWM modules can control two independent 3-phase inverters; each running a motor.

As in the cases shown in the previous sections, we have a choice of running each inverter at a different frequency (module 1 and module 4 are masters as in [Figure 19-59](#)), or both inverters can be synchronized by using one master (module 1) and five slaves. In this case, the frequency of modules 4, 5, and 6 (all equal) can be integer multiples of the frequency for modules 1, 2, 3 (also all equal).

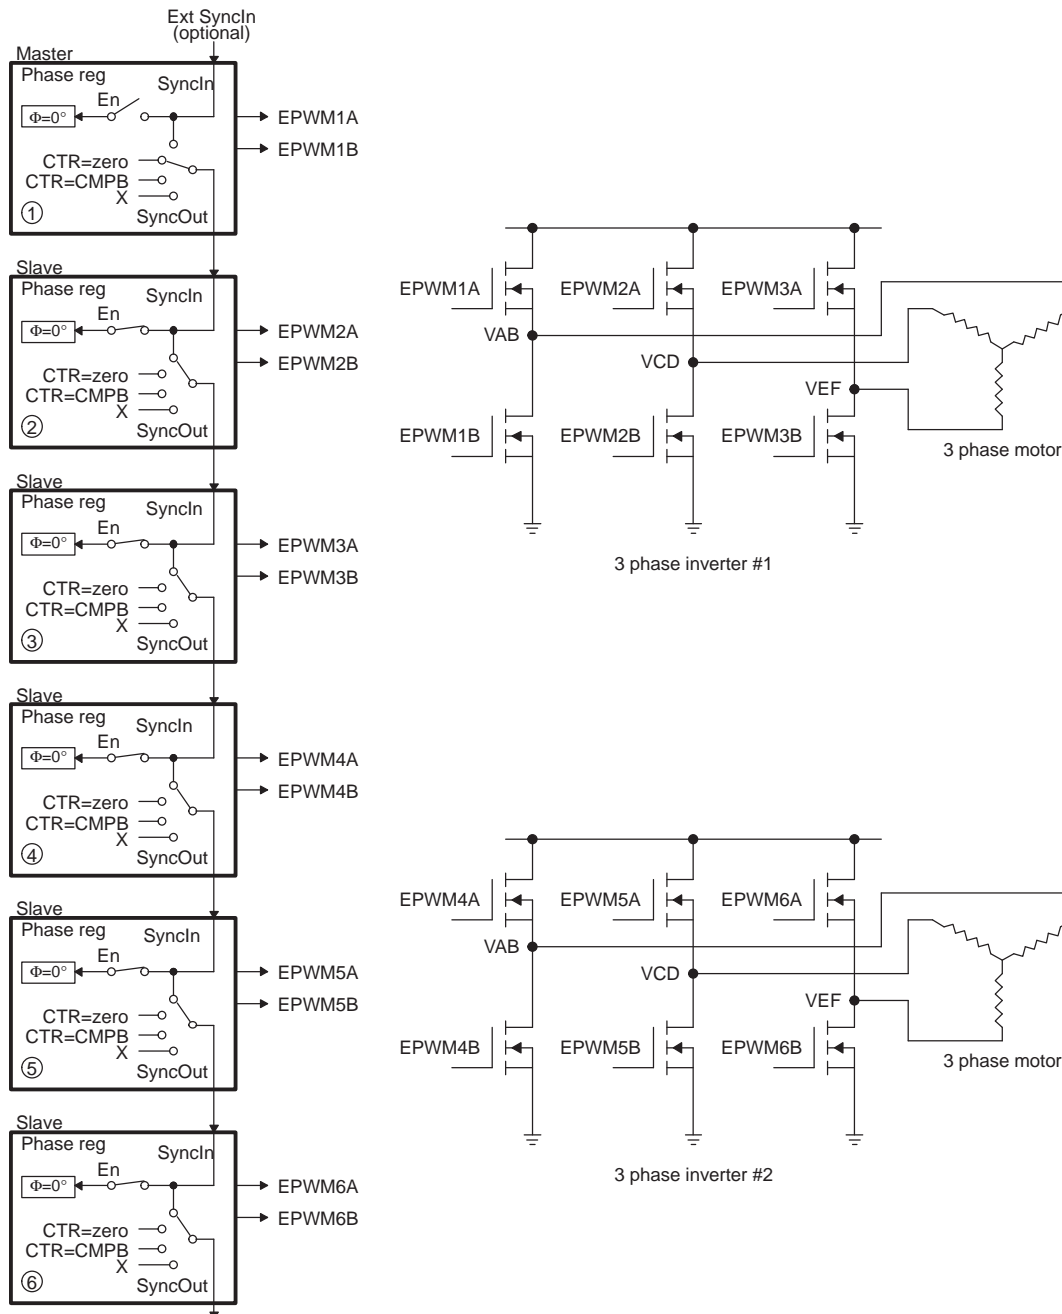

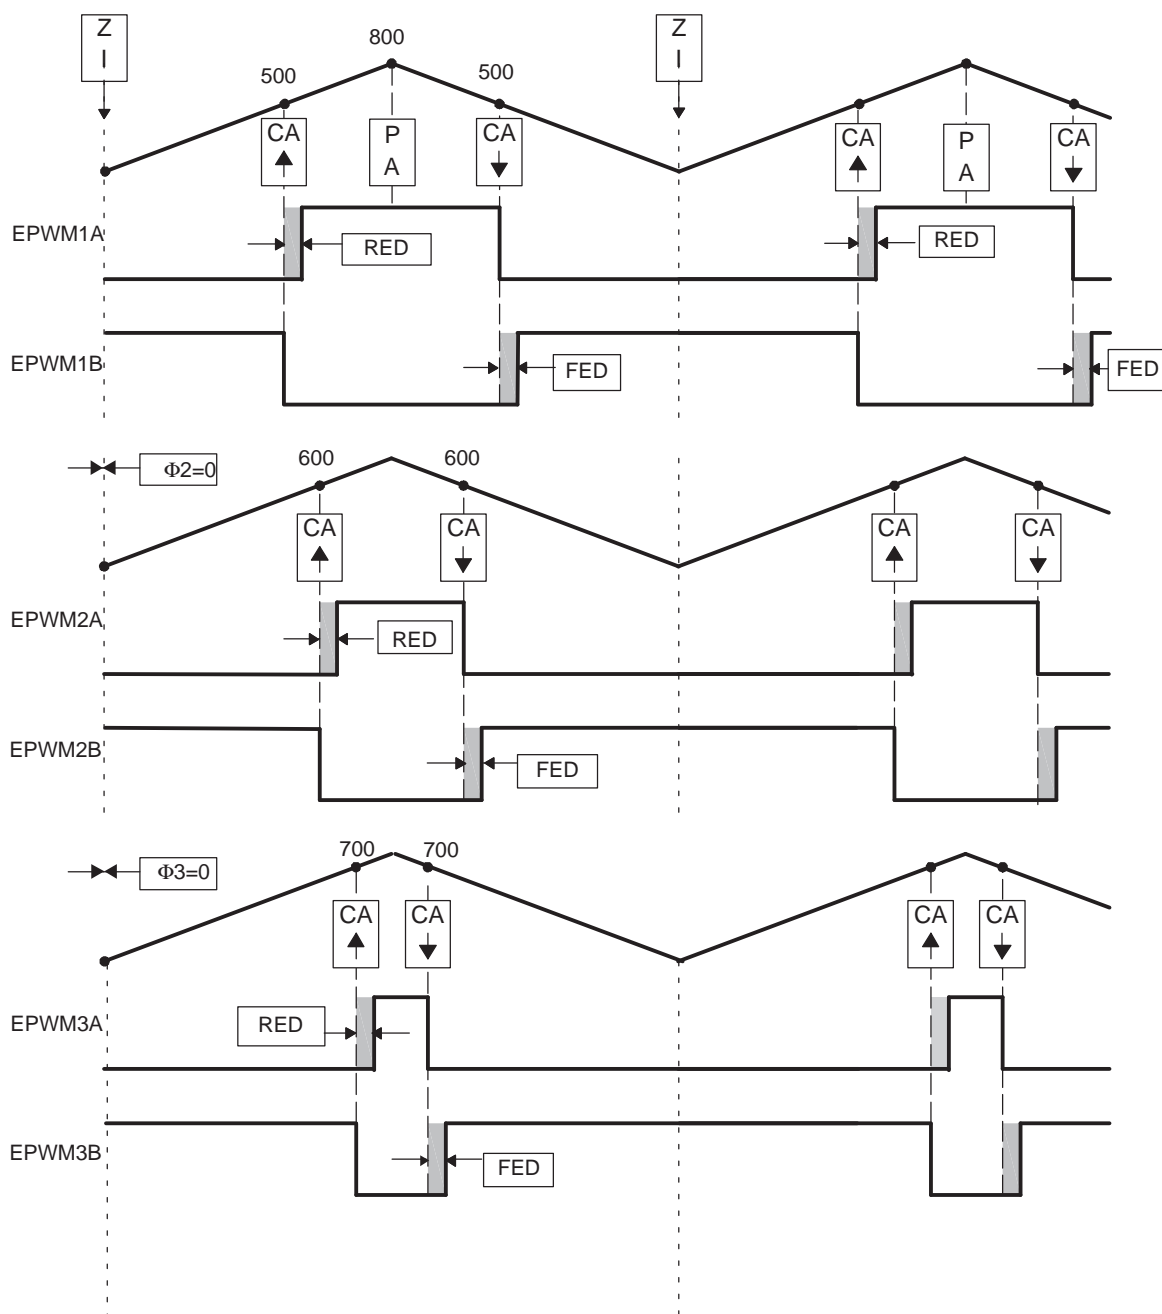

Figure 19-59. Control of Dual 3-Phase Inverter Stages as Is Commonly Used in Motor Control

Figure 19-60. 3-Phase Inverter Waveforms for Figure 19-59 (Only One Inverter Shown)

19.3.7 Practical Applications Using Phase Control Between PWM Modules

So far, none of the examples have made use of the phase register (TBPHS). It has either been set to zero or its value has been a don't care. However, by programming appropriate values into TBPHS, multiple PWM modules can address another class of applications that rely on phase relationship between stages for correct operation. As described in the TB module section, a PWM module can be configured to allow a SyncIn pulse to cause the TBPHS register to be loaded into the TBCTR register. To illustrate this concept, [Figure 19-61](#) shows a master and slave module with a phase relationship of 120°, that is, the slave leads the master.

Figure 19-61. Configuring Two PWM Modules for Phase Control

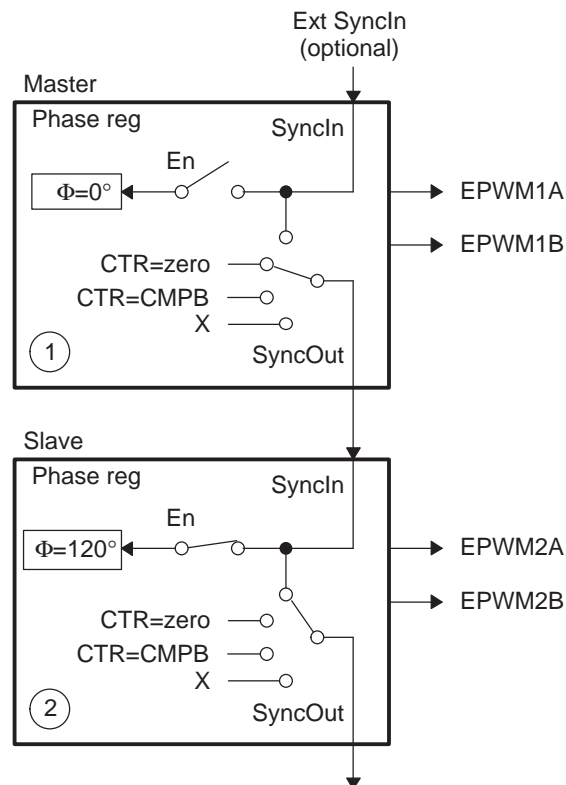

Figure 19-62 shows the associated timing waveforms for this configuration. Here, TBPRD = 600 for both master and slave. For the slave, TBPHS = 200 (that is, $200/600 \times 360^\circ = 120^\circ$). Whenever the master generates a SyncIn pulse (CTR = PRD), the value of TBPHS = 200 is loaded into the slave TBCTR register so the slave time-base is always leading the master's time-base by 120° .

Figure 19-62. Timing Waveforms Associated With Phase Control Between 2 Modules

19.4 ePWM Module Control and Status Registers

Table 19-22 lists the memory-mapped registers for the ePWM Module Control and Status Registers. All register offset addresses not listed in **Table 19-22** should be considered as reserved locations and the register contents should not be modified. The base address for the control registers is FCF7 8C00h for ePWM1, FCF7 8D00h for ePWM2, FCF7 8E00h for ePWM3, FCF7 8F00h for ePWM4, FCF7 9000h for ePWM5, FCF7 9100h for ePWM6, and FCF7 9200h for ePWM7.

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

Table 19-23. TBSTS Register Field Descriptions

| Bit | Field | Type | Reset | Description |
|------|----------|------|-------|---|
| 15-3 | RESERVED | R | 0h | Reserved |
| 2 | CTRMAX | R | 0h | Time-Base Counter Max Latched Status Bit 0h = Reading a 0 indicates the time-base counter never reached its maximum value. Writing a 0 will have no effect. 1h = Reading a 1 on this bit indicates that the time-base counter reached the max value 0xFFFF. Writing a 1 to this bit will clear the latched event. |
| 1 | SYNCl | R/W | 0h | Input Synchronization Latched Status Bit 0h = Writing a 0 will have no effect. Reading a 0 indicates no external synchronization event has occurred. 1h = Reading a 1 on this bit indicates that an external synchronization event has occurred (EPWMxSYNCl). Writing a 1 to this bit will clear the latched event. |
| 0 | CTRDlR | R | 1h | Time-Base Counter Direction Status Bit. At reset, the counter is frozen, therefore, this bit has no meaning. To make this bit meaningful, you must first set the appropriate mode via TBCTL[CTRMODE]. 0h = Time-Base Counter is currently counting down. 1h = Time-Base Counter is currently counting up. |

19.4.2 TBCTL Register (Offset = 2h) [reset = 83h]

TBCTL is shown in [Figure 19-64](#) and described in [Table 19-24](#).

Figure 19-64. TBCTL Register

| 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 |

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

Table 19-24. TBCTL Register Field Descriptions

| Bit | Field | Type | Reset | Description |
|-------|-----------|------|-------|--|
| 15-14 | FREE_SOFT | R/W | 0h | Emulation Mode Bits. These bits select the behavior of the ePWM time-base counter during emulation events: 0h = Stop after the next time-base counter increment or decrement. 1h = Stop when counter completes a whole cycle. In up-count mode, stop when the time-base counter = period (TBCTR = TBPRD). In down-count mode, stop when the time-base counter = 0x0000 (TBCTR = 0x0000). In up-down-count mode, stop when the time-base counter = 0x0000 (TBCTR = 0x0000). 2h = Free run 3h = Free run |
| 13 | PHSDIR | R/W | 0h | Phase Direction Bit. This bit is only used when the time-base counter is configured in the up-down-count mode. The PHSDIR bit indicates the direction the time-base counter (TBCTR) will count after a synchronization event occurs and a new phase value is loaded from the phase (TBPHS) register. This is irrespective of the direction of the counter before the synchronization event. In the up-count and down-count modes this bit is ignored. 0h = Count down after the synchronization event. 1h = Count up after the synchronization event. |
| 12-10 | CLKDIV | R/W | 0h | Time-base Clock Prescale Bits. These bits determine part of the time-base clock prescale value. $TBCLK = VCLK4 / (HSPCLKDIV \times CLKDIV)$ 0h = /1 (default on reset) 1h = /2 2h = /4 3h = /8 4h = /16 5h = /32 6h = /64 7h = /128 |
| 9-7 | HSPCLKDIV | R/W | 1h | High Speed Time-base Clock Prescale Bits. These bits determine part of the time-base clock prescale value. $TBCLK = VCLK4 / (HSPCLKDIV \times CLKDIV)$ 0h = /1 1h = /2 (default on reset) 2h = /4 3h = /6 4h = /8 5h = /10 6h = /12 7h = /14 |

Table 19-24. TBCTL Register Field Descriptions (continued)

| Bit | Field | Type | Reset | Description |
|-----|-----------|------|-------|---|
| 6 | SWFSYNC | R/W | 0h | Software Forced Synchronization Pulse. This event is ORed with the EPWMxSYNCl input of the ePWM module. SWFSYNC is valid (operates) only when EPWMxSYNCl is selected by SYNCOSSEL = 0. 0h = Writing a 0 has no effect and reads always return a 0. 1h = Writing a 1 forces a one-time synchronization pulse to be generated. |
| 5-4 | SYNCOSSEL | R/W | 0h | Synchronization Output Select. These bits select the source of the EPWMxSYNCO signal. 0h = EPWMxSYNC 1h = CTR = zero: Time-base counter equal to zero (TBCTR = 0x0000) 2h = CTR = CMPB : Time-base counter equal to counter-compare B (TBCTR = CMPB) 3h = Disable EPWMxSYNCO signal |
| 3 | PRDLD | R/W | 0h | Active Period Register Load From Shadow Register Select 0h = The period register (TBPRD) is loaded from its shadow register when the time-base counter, TBCTR, is equal to 0. A write or read to the TBPRD register accesses the shadow register. 1h = Load the TBPRD register immediately without using a shadow register. A write or read to the TBPRD register directly accesses the active register. |
| 2 | PHSEN | R/W | 0h | Counter Register Load From Phase Register Enable 0h = Do not load the time-base counter (TBCTR) from the time-base phase register (TBPHS) 1h = Load the time-base counter with the phase register when an EPWMxSYNCl input signal occurs or when a software synchronization is forced by the SWFSYNC bit, or when a digital compare sync event occurs. |
| 1-0 | CTRMODE | R/W | 3h | Counter Mode. The time-base counter mode is normally configured once and not changed during normal operation. If you change the mode of the counter, the change will take effect at the next TBCLK edge and the current counter value shall increment or decrement from the value before the mode change. These bits set the time-base counter mode of operation as follows: 0h = Up-count mode 1h = Down-count mode 2h = Up-down-count mode 3h = Stop-freeze counter operation (default on reset) |

19.4.3 TBPHS Register (Offset = 4h) [reset = 0h]

TBPHS is shown in [Figure 19-65](#) and described in [Table 19-25](#).

Figure 19-65. TBPHS Register

| | | | | | | | | | | | | | | | |
|--------|----|----|----|----|----|---|---|---|---|---|---|---|---|---|---|

| TBPHS | | | | | | | | | | | | | | | |
| R/W-0h | | | | | | | | | | | | | | | |

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

Table 19-25. TBPHS Register Field Descriptions

| Bit | Field | Type | Reset | Description |
|------|-------|------|-------|--|
| 15-0 | TBPHS | R/W | 0h | These bits set time-base counter phase of the selected ePWM relative to the time-base that is supplying the synchronization input signal. Valid values: 0-FFFFh If TBCTL[PHSEN] = 0, then the synchronization event is ignored and the time-base counter is not loaded with the phase. If TBCTL[PHSEN] = 1, then the time-base counter (TBCTR) will be loaded with the phase (TBPHS) when a synchronization event occurs. The synchronization event can be initiated by the input synchronization signal (EPWMxSYNCI) or by a software forced synchronization. |

19.4.4 TBPRD Register (Offset = 8h) [reset = 0h]

TBPRD is shown in [Figure 19-66](#) and described in [Table 19-26](#).

Figure 19-66. TBPRD Register

| | | | | | | | | | | | | | | | |
|--------|----|----|----|----|----|---|---|---|---|---|---|---|---|---|---|

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

Table 19-29. CMPA Register Field Descriptions

| Bit | Field | Type | Reset | Description |
|------|-------|------|-------|---|
| 15-0 | CMPA | R/W | 0h | <p>The value in the active CMPA register is continuously compared to the time-base counter (TBCTR). When the values are equal, the counter-compare module generates a "time-base counter equal to counter compare A" event. This event is sent to the action-qualifier where it is qualified and converted it into one or more actions. These actions can be applied to either the EPWMxA or the EPWMxB output depending on the configuration of the AQCTLA and AQCTLB registers. The actions that can be defined in the AQCTLA and AQCTLB registers include:</p> <p>Do nothing, the event is ignored. Clear: Pull the EPWMxA and/or EPWMxB signal low Set: Pull the EPWMxA and/or EPWMxB signal high Toggle the EPWMxA and/or EPWMxB signal</p> <p>Shadowing of this register is enabled and disabled by the CMPCTL[SHDWAMODE] bit. By default this register is shadowed. If CMPCTL[SHDWAMODE] = 0, then the shadow is enabled and any write or read will automatically go to the shadow register. In this case, the CMPCTL[LOADAMODE] bit field determines which event will load the active register from the shadow register. Before a write, the CMPCTL[SHDWAFULL] bit can be read to determine if the shadow register is currently full. If CMPCTL[SHDWAMODE] = 1, then the shadow register is disabled and any write or read will go directly to the active register, that is the register actively controlling the hardware. In either mode, the active and shadow registers share the same memory map address.</p> |

19.4.8 AQCTLA Register (Offset = 14h) [reset = 0h]

AQCTLA is shown in [Figure 19-70](#) and described in [Table 19-30](#).

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

Table 19-34. DBCTL Register Field Descriptions

| Bit | Field | Type | Reset | Description |
|------|-----------|------|-------|---|
| 15 | HALFCYCLE | R/W | 0h | Half Cycle Clocking Enable Bit: 0h = Full cycle clocking enabled. The dead-band counters are clocked at the TBCLK rate. 1h = Half cycle clocking enabled. The dead-band counters are clocked at TBCLK x 2. |
| 14-6 | RESERVED | R | 0h | Reserved |
| 5-4 | IN_MODE | R/W | 0h | Dead Band Input Mode Control. Bit 5 controls the S5 switch and bit 4 controls the S4 switch shown in . This allows you to select the input source to the falling-edge and rising-edge delay. To produce classical dead-band waveforms the default is EPWMxA In is the source for both falling and rising-edge delays. 0h = EPWMxA In (from the action-qualifier) is the source for both falling-edge and rising-edge delay. 1h = EPWMxB In (from the action-qualifier) is the source for rising-edge delayed signal. EPWMxA In (from the action-qualifier) is the source for falling-edge delayed signal. 2h = EPWMxA In (from the action-qualifier) is the source for rising-edge delayed signal. EPWMxB In (from the action-qualifier) is the source for falling-edge delayed signal. 3h = EPWMxB In (from the action-qualifier) is the source for both rising-edge delay and falling-edge delayed signal. |
| 3-2 | POLSEL | R/W | 0h | Polarity Select Control. Bit 3 controls the S3 switch and bit 2 controls the S2 switch shown in . This allows you to selectively invert one of the delayed signals before it is sent out of the dead-band submodule. The following descriptions correspond to classical upper/lower switch control as found in one leg of a digital motor control inverter. These assume that DBCTL[OUT_MODE] = 1,1 and DBCTL[IN_MODE] = 0,0. Other enhanced modes are also possible, but not regarded as typical usage modes. 0h = Active high (AH) mode. Neither EPWMxA nor EPWMxB is inverted (default). 1h = Active low complementary (ALC) mode. EPWMxA is inverted. 2h = Active high complementary (AHC). EPWMxB is inverted. 3h = Active low (AL) mode. Both EPWMxA and EPWMxB are inverted. |

Table 19-34. DBCTL Register Field Descriptions (continued)

| Bit | Field | Type | Reset | Description |
|-----|----------|------|-------|--|
| 1-0 | OUT_MODE | R/W | 0h | <p>Dead-band Output Mode Control. Bit 1 controls the S1 switch and bit 0 controls the S0 switch shown in .</p> <p>This allows you to selectively enable or bypass the dead-band generation for the falling-edge and rising-edge delay.</p> <p>0h = Dead-band generation is bypassed for both output signals. In this mode, both the EPWMxA and EPWMxB output signals from the action-qualifier are passed directly to the PWM-chopper submodule. In this mode, the POLSEL and IN_MODE bits have no effect.</p> <p>1h = Disable rising-edge delay. The EPWMxA signal from the action-qualifier is passed straight through to the EPWMxA input of the PWM-chopper submodule. The falling-edge delayed signal is seen on output EPWMxB. The input signal for the delay is determined by DBCTL[IN_MODE].</p> <p>2h = The rising-edge delayed signal is seen on output EPWMxA. The input signal for the delay is determined by DBCTL[IN_MODE]. Disable falling-edge delay. The EPWMxB signal from the action-qualifier is passed straight through to the EPWMxB input of the PWM-chopper submodule.</p> <p>3h = Dead-band is fully enabled for both rising-edge delay on output EPWMxA and falling-edge delay on output EPWMxB. The input signal for the delay is determined by DBCTL[IN_MODE].</p> |

19.4.17 TZSEL Register (Offset = 26h) [reset = 0h]

TZSEL is shown in Figure 19-79 and described in Table 19-39.

One-Shot (OSHT) Trip-zone enable/disable (bits 15-8). When any of the enabled pins go low, a one-shot trip event occurs for this ePWM module. When the event occurs, the action defined in the TZCTL register is taken on the EPWMxA and EPWMxB outputs. The one-shot trip condition remains latched until the user clears the condition via the TZCLR register. Cycle-by-Cycle (CBC) Trip-zone enable/disable (bits 7-0).

When any of the enabled pins go low, a cycle-by-cycle trip event occurs for this ePWM module. When the event occurs, the action defined in the TZCTL register is taken on the EPWMxA and EPWMxB outputs. A cycle-by-cycle trip condition is automatically cleared when the time-base counter reaches zero.

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

Table 19-43. TZFLG Register Field Descriptions

| Bit | Field | Type | Reset | Description |
|------|----------|------|-------|---|
| 15-7 | RESERVED | R | 0h | Reserved |
| 6 | DCBEVT2 | R | 0h | Latched Status Flag for Digital Compare Output B Event 2 0h = Indicates no trip event has occurred on DCBEVT2 1h = Indicates a trip event has occurred for the event defined for DCBEVT2 |
| 5 | DCBEVT1 | R | 0h | Latched Status Flag for Digital Compare Output B Event 1 0h = Indicates no trip event has occurred on DCBEVT1 1h = Indicates a trip event has occurred for the event defined for DCBEVT1 |
| 4 | DCAEVT2 | R | 0h | Latched Status Flag for Digital Compare Output A Event 2 0h = Indicates no trip event has occurred on DCAEVT2 1h = Indicates a trip event has occurred for the event defined for DCAEVT2 |
| 3 | DCAEVT1 | R | 0h | Latched Status Flag for Digital Compare Output A Event 1 0h = Indicates no trip event has occurred on DCAEVT1 1h = Indicates a trip event has occurred for the event defined for DCAEVT1 |
| 2 | OST | R | 0h | Latched Status Flag for A One-Shot Trip Event. This bit is cleared by writing the appropriate value to the TZCLR register. 0h = No one-shot trip event has occurred. 1h = Indicates a trip event has occurred on a pin selected as a one-shot trip source. |
| 1 | CBC | R | 0h | Latched Status Flag for Cycle-By-Cycle Trip Event. This bit is cleared by writing the appropriate value to the TZCLR register. 0h = No cycle-by-cycle trip event has occurred. 1h = Indicates a trip event has occurred on a signal selected as a cycle-by-cycle trip source. The TZFLG.CBC bit will remain set until it is manually cleared by the user. If the cycle-by-cycle trip event is still present when the CBC bit is cleared, then CBC will be immediately set again. The specified condition on the signal is automatically cleared when the ePWM time-base counter reaches zero (TBCTR = 0x0000) if the trip condition is no longer present. The condition on the signal is only cleared when the TBCTR = 0x0000 no matter where in the cycle the CBC flag is cleared. |
| 0 | INT | R | 0h | Latched Trip Interrupt Status Flag. No further EPWMx_TZINT VIM interrupts will be generated until this flag is cleared. If the interrupt flag is cleared when either CBC or OST is set, then another interrupt pulse will be generated. Clearing all flag bits will prevent further interrupts. This bit is cleared by writing the appropriate value to the TZCLR register. 0h = Indicates no interrupt has been generated. 1h = Indicates an EPWMx_TZINT VIM interrupt was generated because of a trip condition. |

19.4.22 ETSEL Register (Offset = 30h) [reset = 0h]

| 15-14 | SOCBCNT | R | 0h | ePWM ADC Start-of-Conversion B Event (EPWMxSOCB) Counter Register. These bits indicate how many selected ETSEL[SOCBSEL] events have occurred: 0h = No events have occurred. 1h = 1 event has occurred. 2h = 2 events have occurred. 3h = 3 events have occurred. |
| 13-12 | SOCBPRD | R/W | 0h | ePWM ADC Start-of-Conversion B Event (EPWMxSOCB) Period Select. These bits determine how many selected ETSEL[SOCBSEL] events need to occur before an EPWMxSOCB pulse is generated. To be generated, the pulse must be enabled (ETSEL[SOCBEN] = 1). The SOCB pulse will be generated even if the status flag is set from a previous start of conversion (ETFLG[SOCB] = 1). Once the SOCB pulse is generated, the ETPS[SOCBCNT] bits will automatically be cleared. 0h = Disable the SOCB event counter. No EPWMxSOCB pulse will be generated 1h = Generate the EPWMxSOCB pulse on the first event: ETPS[SOCBCNT] = 0,1 2h = Generate the EPWMxSOCB pulse on the second event: ETPS[SOCBCNT] = 1,0 3h = Generate the EPWMxSOCB pulse on the third event: ETPS[SOCBCNT] = 1,1 |
| 11-10 | SOCACNT | R | 0h | ePWM ADC Start-of-Conversion A Event (EPWMxSOCA) Counter Register. These bits indicate how many selected ETSEL[SOCASEL] events have occurred: 0h = No events have occurred. 1h = 1 event has occurred. 2h = 2 events have occurred. 3h = 3 events have occurred. |
| 9-8 | SOCAPRD | R/W | 0h | ePWM ADC Start-of-Conversion A Event (EPWMxSOCA) Period Select. These bits determine how many selected ETSEL[SOCASEL] events need to occur before an EPWMxSOCA pulse is generated. To be generated, the pulse must be enabled (ETSEL[SOCASEN] = 1). The SOCA pulse will be generated even if the status flag is set from a previous start of conversion (ETFLG[SOCA] = 1). Once the SOCA pulse is generated, the ETPS[SOCACNT] bits will automatically be cleared. 0h = Disable the SOCA event counter. No EPWMxSOCA pulse will be generated 1h = Generate the EPWMxSOCA pulse on the first event: ETPS[SOCACNT] = 0,1 2h = Generate the EPWMxSOCA pulse on the second event: ETPS[SOCACNT] = 1,0 3h = Generate the EPWMxSOCA pulse on the third event: ETPS[SOCACNT] = 1,1 |

Table 19-47. ETPS Register Field Descriptions (continued)

| Bit | Field | Type | Reset | Description |
|-----|----------|------|-------|--|
| 7-4 | RESERVED | R | 0h | Reserved |
| 3-2 | INTCNT | R | 0h | <p>ePWM Interrupt Event (EPWMx_INT) Counter Register. These bits indicate how many selected ETSEL[INTSEL] events have occurred. These bits are automatically cleared when an interrupt pulse is generated. If interrupts are disabled, ETSEL[INT] = 0 or the interrupt flag is set, ETFLG[INT] = 1, the counter will stop counting events when it reaches the period value ETPS[INTCNT] = ETPS[INTPRD].</p> <p>0h = No events have occurred. 1h = 1 event has occurred. 2h = 2 events have occurred. 3h = 3 events have occurred.</p> |
| 1-0 | INTPRD | R/W | 0h | <p>ePWM Interrupt (EPWMx_INT) Period Select. These bits determine how many selected ETSEL[INTSEL] events need to occur before an interrupt is generated. To be generated, the interrupt must be enabled (ETSEL[INT] = 1). If the interrupt status flag is set from a previous interrupt (ETFLG[INT] = 1) then no interrupt will be generated until the flag is cleared via the ETCLR[INT] bit. This allows for one interrupt to be pending while another is still being serviced. Once the interrupt is generated, the ETPS[INTCNT] bits will automatically be cleared.</p> <p>Writing a INTPRD value that is the same as the current counter value will trigger an interrupt if it is enabled and the status flag is clear.</p> <p>Writing a INTPRD value that is less than the current counter value will result in an undefined state.</p> <p>If a counter event occurs at the same instant as a new zero or non-zero INTPRD value is written, the counter is incremented.</p> <p>0h = Disable the interrupt event counter. No interrupt will be generated and ETFRC[INT] is ignored. 1h = Generate an interrupt on the first event INTCNT = 01 (first event) 2h = Generate interrupt on ETPS[INTCNT] = 1,0 (second event) 3h = Generate interrupt on ETPS[INTCNT] = 1,1 (third event)</p> |

19.4.26 ETFRC Register (Offset = 38h) [reset = 0h]

ETFRC is shown in [Figure 19-88](#) and described in [Table 19-48](#).

| Bit | Field | Type | Reset | Description |
|------|--------|------|-------|--|
| 15-0 | OFFSET | R | 0h | Blanking Window Offset. Valid values: 0-FFFFh These 16-bits specify the number of TBCLK cycles from the blanking window reference to the point when the blanking window is applied. The blanking window reference is either period or zero as defined by the DCFCTL[PULSESEL] bit. This offset register is shadowed and the active register is loaded at the reference point defined by DCFCTL[PULSESEL]. The offset counter is also initialized and begins to count down when the active register is loaded. When the counter expires, the blanking window is applied. If the blanking window is currently active, then the blanking window counter is restarted. |

19.4.34 DCCAPCTL Register (Offset = 6Ah) [reset = 0h]

DCCAPCTL is shown in [Figure 19-96](#) and described in [Table 19-56](#).

LEGEND: R/W = Read/Write; R = Read only; W1toCl = Write 1 to clear bit; -n = value after reset

Table 19-58. DCFFSETCNT Register Field Descriptions

| Bit | Field | Type | Reset | Description |
|------|----------|------|-------|--|
| 15-0 | FFSETCNT | R | 0h | Blanking Offset Counter. Valid values: 0-FFFFh These 16-bits are read only and indicate the current value of the offset counter. The counter counts down to zero and then stops until it is re-loaded on the next period or zero event as defined by the DCFCTL[PULSESEL] bit. The offset counter is not affected by the free/soft emulation bits. That is, it will always continue to count down if the device is halted by a emulation stop. |

19.4.37 DCCAP Register (Offset = 70h) [reset = 0h]

DCCAP is shown in [Figure 19-99](#) and described in [Table 19-59](#).

Figure 19-99. DCCAP Register

| | | | | | | | | | | | | | | | |

Table 19-60. DCFWINDOWCNT Register Field Descriptions

| Bit | Field | Type | Reset | Description |
|------|-----------|------|-------|--|
| 15-8 | RESERVED | R | 0h | Any writes to these bit(s) must always have a value of 0. |
| 7-0 | WINDOWCNT | R | 0h | Blanking Window Counter. Valid value: 0-FFh These 8 bits are read only and indicate the current value of the window counter. The counter counts down to zero and then stops until it is re-loaded when the offset counter reaches zero again. |

Enhanced Capture (eCAP) Module

The enhanced Capture (eCAP) module is essential in systems where accurate timing of external events is important. This microcontroller implements 6 instances of the eCAP module.

| Topic | Page |
|---|------------|
| 20.1 Introduction | 835 |
| 20.2 Description | 835 |
| 20.3 Capture and APWM Operating Mode | 836 |
| 20.4 Capture Mode Description | 837 |
| 20.5 ECAP Registers | 843 |
| 20.6 Application of the ECAP Module..... | 859 |
| 20.7 Application of the APWM Mode | 868 |

20.1 Introduction

Uses for eCAP include:

- Speed measurements of rotating machinery (for example, toothed sprockets sensed via Hall sensors)
- Elapsed time measurements between position sensor pulses
- Period and duty cycle measurements of pulse train signals
- Decoding current or voltage amplitude derived from duty cycle encoded current/voltage sensors

The eCAP module described in this guide includes the following features:

- 4-event time-stamp registers (each 32 bits)
- Edge polarity selection for up to four sequenced time-stamp capture events
- Interrupt on either of the four events
- Single shot capture of up to four event time-stamps
- Continuous mode capture of time-stamps in a four-deep circular buffer
- Absolute time-stamp capture
- Difference (Delta) mode time-stamp capture
- All above resources dedicated to a single input pin
- When not used in capture mode, the ECAP module can be configured as a single channel PWM output

20.2 Description

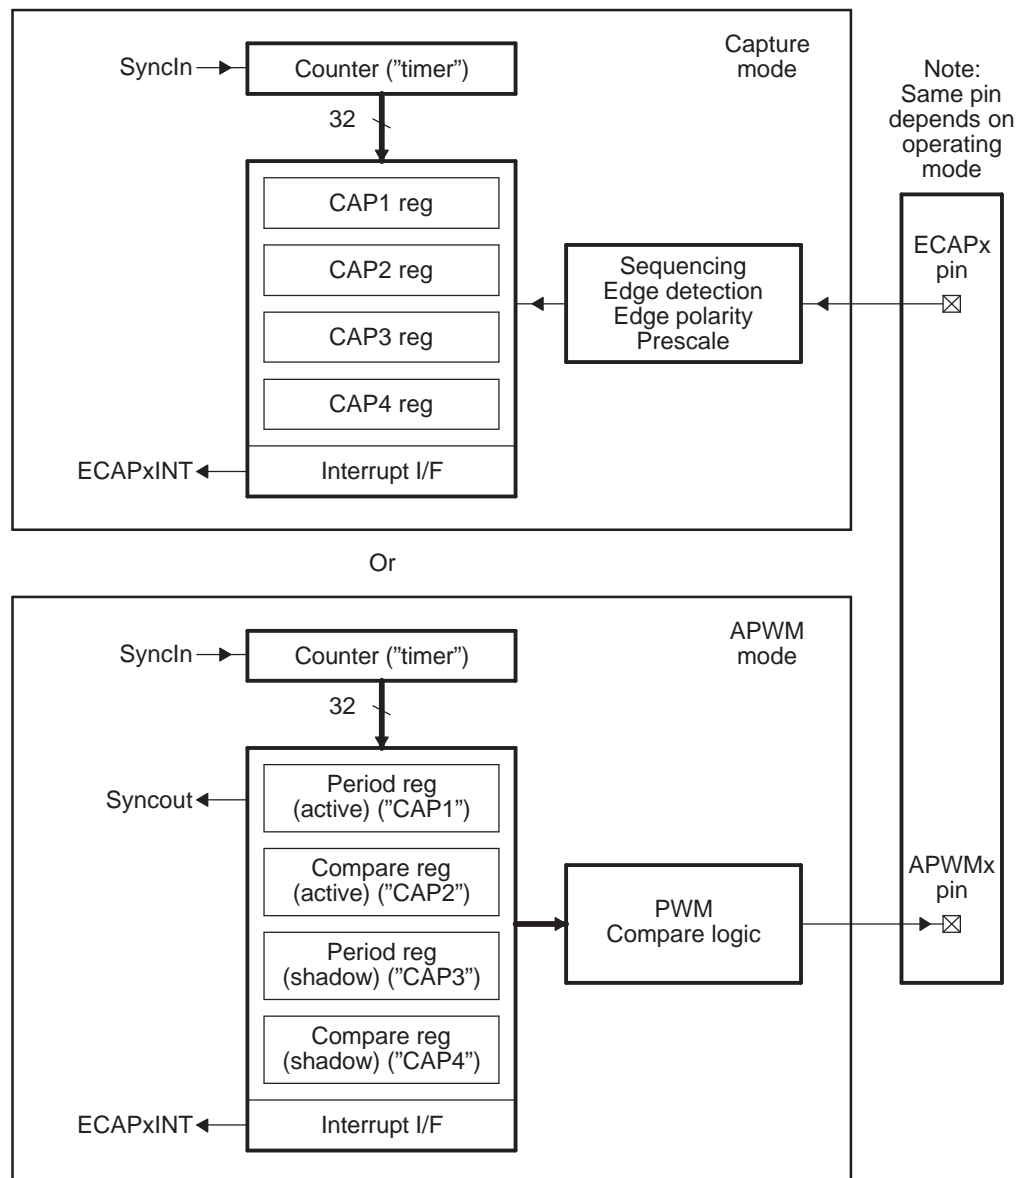

In the context of this chapter, one eCAP channel has the following independent key resources:

- Dedicated input capture pin
- 32-bit time base (counter)
- 4 × 32-bit time-stamp capture registers (CAP1-CAP4)
- 4-stage sequencer (Modulo4 counter) that is synchronized to external events, ECAP pin rising/falling edges
- Independent edge polarity (rising/falling edge) selection for all 4 events
- Input capture signal prescaling (from 2 to 62)
- One-shot compare register (2 bits) to freeze captures after 1 to 4 time-stamp events
- Control for continuous time-stamp captures using a 4-deep circular buffer (CAP1-CAP4) scheme
- Interrupt capabilities on any of the 4 capture events

20.3 Capture and APWM Operating Mode

You can use the eCAP module resources to implement a single-channel PWM generator (with 32 bit capabilities) when it is not being used for input captures. The counter operates in count-up mode, providing a time-base for asymmetrical pulse width modulation (PWM) waveforms. The CAP1 and CAP2 registers become the active period and compare registers, respectively, while CAP3 and CAP4 registers become the period and capture shadow registers, respectively. Figure 20-1 is a high-level view of both the capture and auxiliary pulse-width modulator (APWM) modes of operation.

Figure 20-1. Capture and APWM Modes of Operation

- A A single pin is shared between CAP and APWM functions. In capture mode, it is an input; in APWM mode, it is an output.
- B In APWM mode, writing any value to CAP1/CAP2 active registers also writes the same value to the corresponding shadow registers CAP3/CAP4. This emulates immediate mode. Writing to the shadow registers CAP3/CAP4 invokes the shadow mode.

20.4 Capture Mode Description

Figure 20-2 shows the various components that implement the capture function.

Figure 20-2. Capture Function Diagram

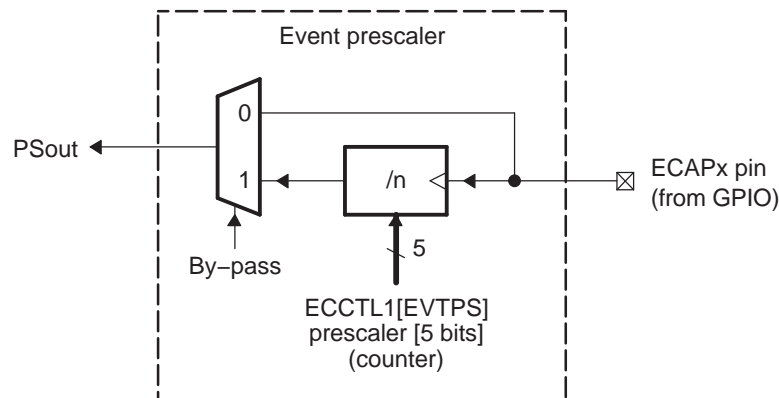

20.4.1 Event Prescaler

- An input capture signal (pulse train) can be prescaled by $N = 2-62$ (in multiples of 2) or can bypass the prescaler.

This is useful when very high frequency signals are used as inputs. [Figure 20-3](#) shows a functional diagram and [Figure 20-4](#) shows the operation of the prescale function.

Figure 20-3. Event Prescale Control

- A When a prescale value of 1 is chosen (that is, $ECCTL1[13:9] = 0,0,0,0,0$) the input capture signal by-passes the prescale logic completely.

Figure 20-4. Prescale Function Waveforms

20.4.2 Edge Polarity Select and Qualifier

- Four independent edge polarity (rising edge/falling edge) selection MUXes are used, one for each capture event.
- Each edge (up to 4) is event qualified by the Modulo4 sequencer.
- The edge event is gated to its respective CAPx register by the Mod4 counter. The CAPx register is loaded on the falling edge.

20.4.3 Continuous/One-Shot Control

- The Mod4 (2 bit) counter is incremented via edge qualified events (CEVT1-CEVT4).
- The Mod4 counter continues counting (0->1->2->3->0) and wraps around unless stopped.
- A 2-bit stop register is used to compare the Mod4 counter output, and when equal stops the Mod4 counter and inhibits further loads of the CAP1-CAP4 registers. This occurs during one-shot operation.

The continuous/one-shot block controls the start/stop and reset (zero) functions of the Mod4 counter via a mono-shot type of action that can be triggered by the stop-value comparator and re-armed via software control.

Once armed, the eCAP module waits for 1-4 (defined by stop-value) capture events before freezing both the Mod4 counter and contents of CAP1-4 registers (that is, time-stamps).

Re-arming prepares the eCAP module for another capture sequence. Also re-arming clears (to zero) the Mod4 counter and permits loading of CAP1-4 registers again, providing the CAPLDEN bit is set.

In continuous mode, the Mod4 counter continues to run (0->1->2->3->0, the one-shot action is ignored, and capture values continue to be written to CAP1-4 in a circular buffer sequence.

Figure 20-5. Details of the Continuous/One-shot Block

20.4.4 32-Bit Counter and Phase Control

This counter provides the time-base for event captures, and is clocked via the system clock.

A phase register is provided to achieve synchronization with other counters, via a hardware and software forced sync. This is useful in APWM mode when a phase offset between modules is needed.

On any of the four event loads, an option to reset the 32-bit counter is given. This is useful for time difference capture. The 32-bit counter value is captured first, then it is reset to 0 by any of the LD1-LD4 signals.

Figure 20-6. Details of the Counter and Synchronization Block

20.4.5 CAP1-CAP4 Registers

These 32-bit registers are fed by the 32-bit counter timer bus, CTR[0-31] and are loaded (that is, capture a time-stamp) when their respective LD inputs are strobed.

Loading of the capture registers can be inhibited via control bit CAPLDEN. During one-shot operation, this bit is cleared (loading is inhibited) automatically when a stop condition occurs, that is, StopValue = Mod4.

CAP1 and CAP2 registers become the active period and compare registers, respectively, in APWM mode.

CAP3 and CAP4 registers become the respective shadow registers (APRD and ACMP) for CAP1 and CAP2 during APWM operation.

20.4.6 Interrupt Control

An interrupt can be generated on capture events (CEVT1-CEVT4, CTROVF) or APWM events (CTR = PRD, CTR = CMP).

A counter overflow event (FFFFFFFF->00000000) is also provided as an interrupt source (CTROVF).

The capture events are edge and sequencer qualified (that is, ordered in time) by the polarity select and Mod4 gating, respectively.

One of these events can be selected as the interrupt source (from the eCAPx module) going to the PIE.

Seven interrupt events (CEVT1, CEVT2, CEVT3, CEVT4, CNTOVF, CTR=PRD, CTR=CMP) can be generated. The interrupt enable register (ECEINT) is used to enable/disable individual interrupt event sources. The interrupt flag register (ECFLG) indicates if any interrupt event has been latched and contains the global interrupt flag bit (INT). An interrupt pulse is generated to the PIE only if any of the interrupt events are enabled, the flag bit is 1, and the INT flag bit is 0. The interrupt service routine must clear the global interrupt flag bit and the serviced event via the interrupt clear register (ECCLR) before any other interrupt pulses are generated. You can force an interrupt event via the interrupt force register (ECFRC). This is useful for test purposes.

Note: The CEVT1, CEVT2, CEVT3, CEVT4 flags are only active in capture mode (ECCTL2[CAP_APWM == 0]). The CTR_PRD, CTR_CMP flags are only valid in APWM mode (ECCTL2[CAP_APWM == 1]). CNTOVF flag is valid in both modes.

Figure 20-7. Interrupts in eCAP Module

20.4.7 Shadow Load and Lockout Control

In capture mode, this logic inhibits (locks out) any shadow loading of CAP1 or CAP2 from APRD and ACMP registers, respectively.

In APWM mode, shadow loading is active and two choices are permitted:

- Immediate - APRD or ACMP are transferred to CAP1 or CAP2 immediately upon writing a new value.
- On period equal, that is, CTR[31:0] = PRD[31:0]

20.4.8 APWM Mode Operation

Main operating highlights of the APWM section:

- The time-stamp counter bus is made available for comparison via 2 digital (32-bit) comparators.
- When CAP1/2 registers are not used in capture mode, their contents can be used as Period and Compare values in APWM mode.
- Double buffering is achieved via shadow registers APRD and ACMP (CAP3/4). The shadow register contents are transferred over to CAP1/2 registers either immediately upon a write, or on a CTR = PRD trigger.
- In APWM mode, writing to CAP1/CAP2 active registers will also write the same value to the corresponding shadow registers CAP3/CAP4. This emulates immediate mode. Writing to the shadow registers CAP3/CAP4 will invoke the shadow mode.
- During initialization, you must write to the active registers for both period and compare. This automatically copies the initial values into the shadow values. For subsequent compare updates, that is, during run-time, you only need to use the shadow registers.

Figure 20-8. PWM Waveform Details Of APWM Mode Operation

The behavior of APWM active high mode (APWMPOL == 0) is as follows:

CMP = 0x00000000, output low for duration of period (0% duty)
 CMP = 0x00000001, output high 1 cycle
 CMP = 0x00000002, output high 2 cycles
 CMP = PERIOD, output high except for 1 cycle (<100% duty)
 CMP = PERIOD+1, output high for complete period (100% duty)
 CMP > PERIOD+1, output high for complete period

The behavior of APWM active low mode (APWMPOL == 1) is as follows:

CMP = 0x00000000, output high for duration of period (0% duty)
 CMP = 0x00000001, output low 1 cycle
 CMP = 0x00000002, output low 2 cycles
 CMP = PERIOD, output low except for 1 cycle (<100% duty)
 CMP = PERIOD+1, output low for complete period (100% duty)
 CMP > PERIOD+1, output low for complete period

20.5 ECAP Registers

[Table 20-1](#) lists the memory-mapped registers for the ECAP. All register offset addresses not listed in [Table 20-1](#) should be considered as reserved locations and the register contents should not be modified. The base address for the control registers is FCF7 9300h for eCAP1, FCF7 9400h for eCAP2, FCF7 9500h for eCAP3, FCF7 9600h for eCAP4, FCF7 9700h for eCAP5, and FCF7 9800h for eCAP6.

Table 20-1. ECAP Registers

| Offset | Acronym | Register Name | Section |
|--------|---------|-------------------------------------|---------------------------------|
| 0h | TSCTR | Time-Stamp Counter | Section 20.5.1 |
| 4h | CTRPHS | Counter Phase Offset Value Register | Section 20.5.2 |

| Bit | Field | Type | Reset | Description |
|------|--------|------|-------|--|
| 31-0 | CTRPHS | R/W | 0h | Counter phase value register that can be programmed for phase lag/lead. This register shadows TSCTR and is loaded into TSCTR upon either a SYNCI event or S/W force via a control bit. Used to achieve phase control synchronization with respect to other eCAP and ePWM time-bases. |

20.5.3 CAP1 Register (Offset = 8h) [reset = 0h]

CAP1 is shown in [Figure 20-11](#) and described in [Table 20-4](#).

In APWM mode, writing to CAP1/CAP2 active registers also writes the same value to the corresponding shadow registers CAP3/CAP4. This emulates immediate mode. Writing to the shadow registers CAP3/CAP4 invokes the shadow mode.

Figure 20-11. CAP1 Register

| | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |

| 9 | CAP_APWM | R/W | 0h | CAP/APWM operating mode select 0h = ECAP module operates in capture mode. This mode forces the following configuration: inhibits TSCTR resets via CTR = PRD event, inhibits shadow loads on CAP1 and CAP2 registers, permits user to enable CAP1 to CAP4 register load, CAPx and APWMx pin operates as a capture input. 1h = ECAP module operates in APWM mode. This mode forces the following configuration: resets TSCTR on CTR = PRD event (period boundary, permits shadow loading on CAP1 and CAP2 registers, disables loading of time-stamps into CAP1 to CAP4 registers, CAPx and APWMx pin operates as a APWM output. |
| 8 | SWSYNC | R/W | 0h | Software-forced Counter (TSCTR) Synchronizing. This provides a convenient software method to synchronize some or all ECAP time bases. In APWM mode, the synchronizing can also be done via the CTR = PRD event. Note: Selection CTR = PRD is meaningful only in APWM mode, however, you can choose it in CAP mode if you find doing so useful. 0h = Writing a 0 has no effect. Reading always returns 0. 1h = Writing a 1 forces a TSCTR shadow load of current ECAP module and any ECAP modules down-stream providing the SYNCO_SEL bits are 0,0. After writing a 1, this bit returns to 0. |
| 7-6 | SYNCO_SEL | R/W | 0h | Sync-Out Select 0h = Select sync-in event to be the sync-out signal (pass through) 1h = Select CTR = PRD event to be the sync-out signal 2h = Disable sync out signal 3h = Disable sync out signal |
| 5 | SYNCl_EN | R/W | 0h | Counter (TSCTR) Sync-In select mode 0h = Disable sync-in option 1h = Enable counter (TSCTR) to be loaded from CTRPHS register upon either a SYNCl signal or a S/W force event. |
| 4 | TSCTRSTOP | R/W | 0h | Time Stamp (TSCTR) Counter Stop (freeze) Control 0h = TSCTR stopped 1h = TSCTR free-running |

Table 20-8. ECCTL2 Register Field Descriptions (continued)

| Bit | Field | Type | Reset | Description |
|-----|-------------|------|-------|--|
| 3 | REARM | R/W | 0h | <p>One-Shot Re-Arming Control, that is, wait for stop trigger.</p> <p>Note: The re-arm function is valid in one shot or continuous mode.</p> <p>0h = Writing a 0 has no effect. Reading always returns 0. 1h = Arms the one-shot sequence as follows: resets the Mod4 counter to 0, unfreezes the Mod4 counter, enables capture register loads.</p> |
| 2-1 | STOP_WRAP | R/W | 1h | <p>Stop value for one-shot mode. This is the number (between 1-4) of captures allowed to occur before the CAP(1-4) registers are frozen, that is, capture sequence is stopped.</p> <p>Notes: STOP_WRAP is compared to Mod4 counter and, when equal, two actions occur: 1) Mod4 counter is stopped (frozen) 2) Capture register loads are inhibited</p> <p>In one-shot mode, further interrupt events are blocked until re-armed.</p> <p>Wrap value for continuous mode. This is the number (between 1-4) of the capture register in which the circular buffer wraps around and starts again.</p> <p>0h = Stop after Capture Event 1 in one-shot mode. Wrap after Capture Event 1 in continuous mode. 1h = Stop after Capture Event 2 in one-shot mode. Wrap after Capture Event 2 in continuous mode. 2h = Stop after Capture Event 3 in one-shot mode. Wrap after Capture Event 3 in continuous mode. 3h = Stop after Capture Event 4 in one-shot mode. Wrap after Capture Event 4 in continuous mode.</p> |
| 0 | CONT_ONESHT | R/W | 0h | <p>Continuous or one-shot mode control. This is applicable only in capture mode.</p> <p>0h = Operate in continuous mode 1h = Operate in one-Shot mode</p> |

20.5.8 ECCTL1 Register (Offset = 2Ah) [reset = 0h]

ECCTL1 is shown in [Figure 20-16](#) and described in [Table 20-9](#).

20.5.10 ECEINT Register (Offset = 2Eh) [reset = 0h]

ECEINT is shown in [Figure 20-18](#) and described in [Table 20-11](#).

The interrupt enable bits (CEVT1, ...) block any of the selected events from generating an interrupt. Events will still be latched into the flag bit (ECFLG register) and can be forced/cleared via the ECFRC/ECCLR registers.

The proper procedure for configuring peripheral modes and interrupts is as follows:

- 1) Disable global interrupts.
- 2) Stop eCAP counter.
- 3) Disable eCAP interrupts.
- 4) Configure peripheral registers.
- 5) Clear spurious eCAP interrupt flags.
- 6) Enable eCAP interrupts.
- 7) Start eCAP counter.
- 8) Enable global interrupts.

20.6 Application of the ECAP Module

The following sections will provide applications examples and code snippets to show how to configure and operate the eCAP module. For clarity and ease of use, the examples use the eCAP “C” header files. Below are useful #defines that will help in the understanding of the examples.

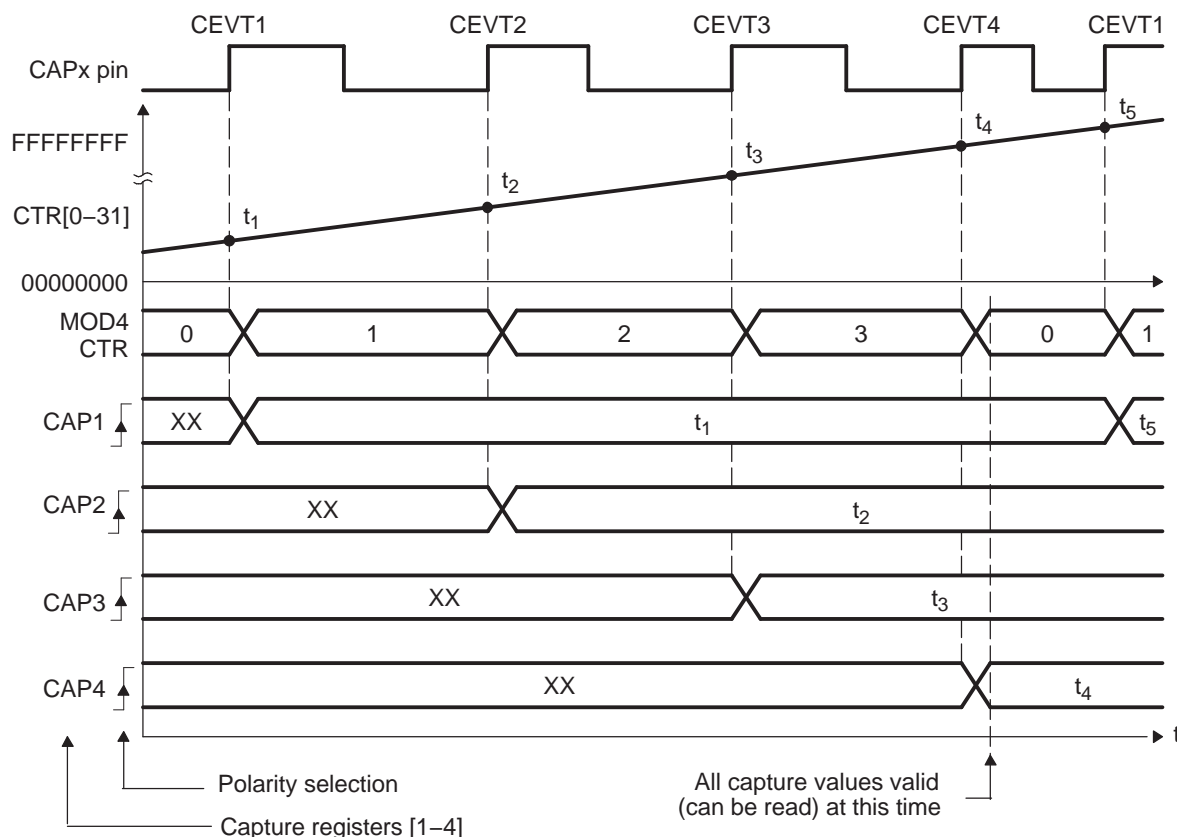

```
// ECCTL1 ( ECAP Control Reg 1)
//=====
// CAPxPOL bits
#define EC_RISING 0x0
#define EC_FALLING 0x1
// CTRRSTx bits
#define EC_ABS_MODE 0x0
#define EC_DELTA_MODE 0x1
// PRESCALE bits
#define EC_BYPASS 0x0
#define EC_DIV1 0x0
#define EC_DIV2 0x1
#define EC_DIV4 0x2
#define EC_DIV6 0x3
#define EC_DIV8 0x4
#define EC_DIV10 0x5
// ECCTL2 ( ECAP Control Reg 2)
//=====
// CONT/ONESHOT bit
#define EC_CONTINUOUS 0x0
#define EC_ONESHOT 0x1
// STOPVALUE bit
#define EC_EVENT1 0x0
#define EC_EVENT2 0x1
#define EC_EVENT3 0x2
#define EC_EVENT4 0x3
// RE-ARM bit
#define EC_ARM 0x1
// TSCTRSTOP bit
#define EC_FREEZE 0x0
#define EC_RUN 0x1
// SYNCO_SEL bit
#define EC_SYNCIN 0x0
#define EC_CTR_PRD 0x1
#define EC_SYNCO_DIS 0x2
// CAP/APWM mode bit
#define EC_CAP_MODE 0x0
#define EC_APWM_MODE 0x1
// APWMPOL bit
#define EC_ACTV_HI 0x0
#define EC_ACTV_LO 0x1
// Generic
#define EC_DISABLE 0x0
#define EC_ENABLE 0x1
#define EC_FORCE 0x1
```

20.6.1 Example 1 - Absolute Time-Stamp Operation Rising Edge Trigger

Figure 20-21 shows an example of continuous capture operation (Mod4 counter wraps around). In this figure, TSCTR counts-up without resetting and capture events are qualified on the rising edge only, this gives period (and frequency) information.

On an event, the TSCTR contents (that is, time-stamp) is first captured, then Mod4 counter is incremented to the next state. When the TSCTR reaches FFFF FFFFh (that is, maximum value), it wraps around to 0000 0000h (not shown in Figure 20-21), if this occurs, the CTROVF (counter overflow) flag is set, and an interrupt (if enabled) occurs, CTROVF (counter overflow) Flag is set, and an Interrupt (if enabled) occurs. Captured Time-stamps are valid at the point indicated by the diagram, that is, after the 4th event, hence event CEVT4 can conveniently be used to trigger an interrupt and the CPU can read data from the CAPx registers.

Figure 20-21. Capture Sequence for Absolute Time-stamp and Rising Edge Detect

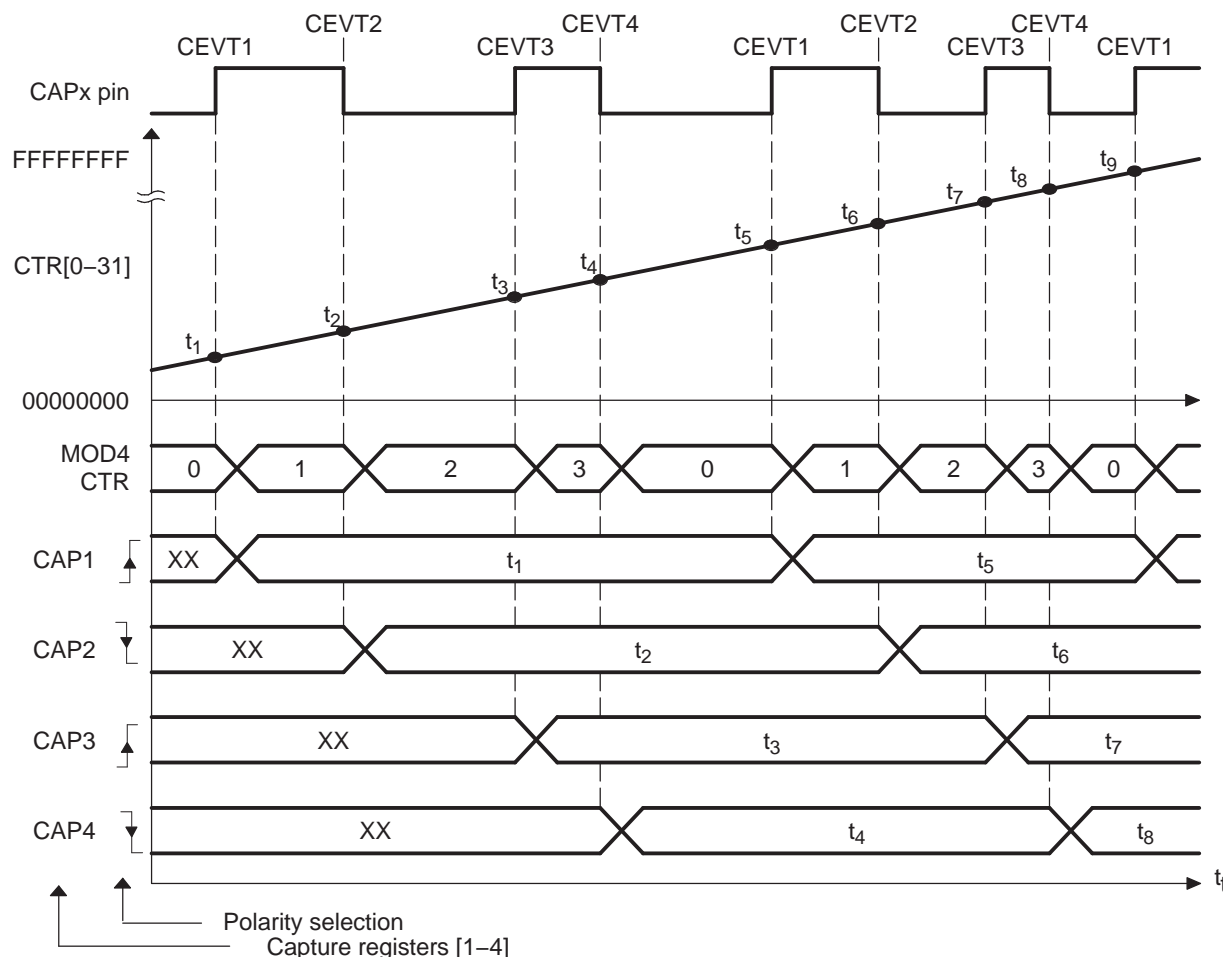

20.6.1.1 Code snippet for CAP mode Absolute Time, Rising Edge Trigger

```
// Code snippet for CAP mode Absolute Time, Rising edge trigger
// Initialization Time
//=====
// ECAP module 1 config
ECap1Regs.ECCTL1.bit.CAP1POL = EC_RISING;
ECap1Regs.ECCTL1.bit.CAP2POL = EC_RISING;
ECap1Regs.ECCTL1.bit.CAP3POL = EC_RISING;
ECap1Regs.ECCTL1.bit.CAP4POL = EC_RISING;
ECap1Regs.ECCTL1.bit.CTRRST1 = EC_ABS_MODE;
ECap1Regs.ECCTL1.bit.CTRRST2 = EC_ABS_MODE;
ECap1Regs.ECCTL1.bit.CTRRST3 = EC_ABS_MODE;
ECap1Regs.ECCTL1.bit.CTRRST4 = EC_ABS_MODE;
ECap1Regs.ECCTL1.bit.CAPLDEN = EC_ENABLE;
ECap1Regs.ECCTL1.bit.PRESCALE = EC_DIV1;

ECap1Regs.ECCTL2.bit.CONT_ONESHT = EC_CONTINUOUS;
ECap1Regs.ECCTL2.bit.SYNCO_SEL = EC_SYNCO_DIS;
ECap1Regs.ECCTL2.bit.SYNCI_EN = EC_DISABLE;
ECap1Regs.ECCTL2.bit.TSCTRSTOP = EC_RUN; // Allow TSCTR to run
// Run Time ( e.g. CEVT4 triggered ISR call)
//=====
TSt1 = ECap1Regs.CAP1; // Fetch Time-Stamp captured at t1
TSt2 = ECap1Regs.CAP2; // Fetch Time-Stamp captured at t2
TSt3 = ECap1Regs.CAP3; // Fetch Time-Stamp captured at t3
TSt4 = ECap1Regs.CAP4; // Fetch Time-Stamp captured at t4
Period1 = TSt2-TSt1; // Calculate 1st period
Period2 = TSt3-TSt2; // Calculate 2nd period
Period3 = TSt4-TSt3; // Calculate 3rd period
```

20.6.2 Example 2 - Absolute Time-Stamp Operation Rising and Falling Edge Trigger

In Figure 20-22 the eCAP operating mode is almost the same as in the previous section except capture events are qualified as either rising or falling edge, this now gives both period and duty cycle information, that is, $\text{Period1} = t_3 - t_1$, $\text{Period2} = t_5 - t_3$, and so on; $\text{Duty Cycle1 (on-time \%)} = (t_2 - t_1) / \text{Period1} \times 100\%$, and so on; $\text{Duty Cycle1 (off-time \%)} = (t_3 - t_2) / \text{Period1} \times 100\%$, and so on.

Figure 20-22. Capture Sequence for Absolute Time-stamp With Rising and Falling Edge Detect

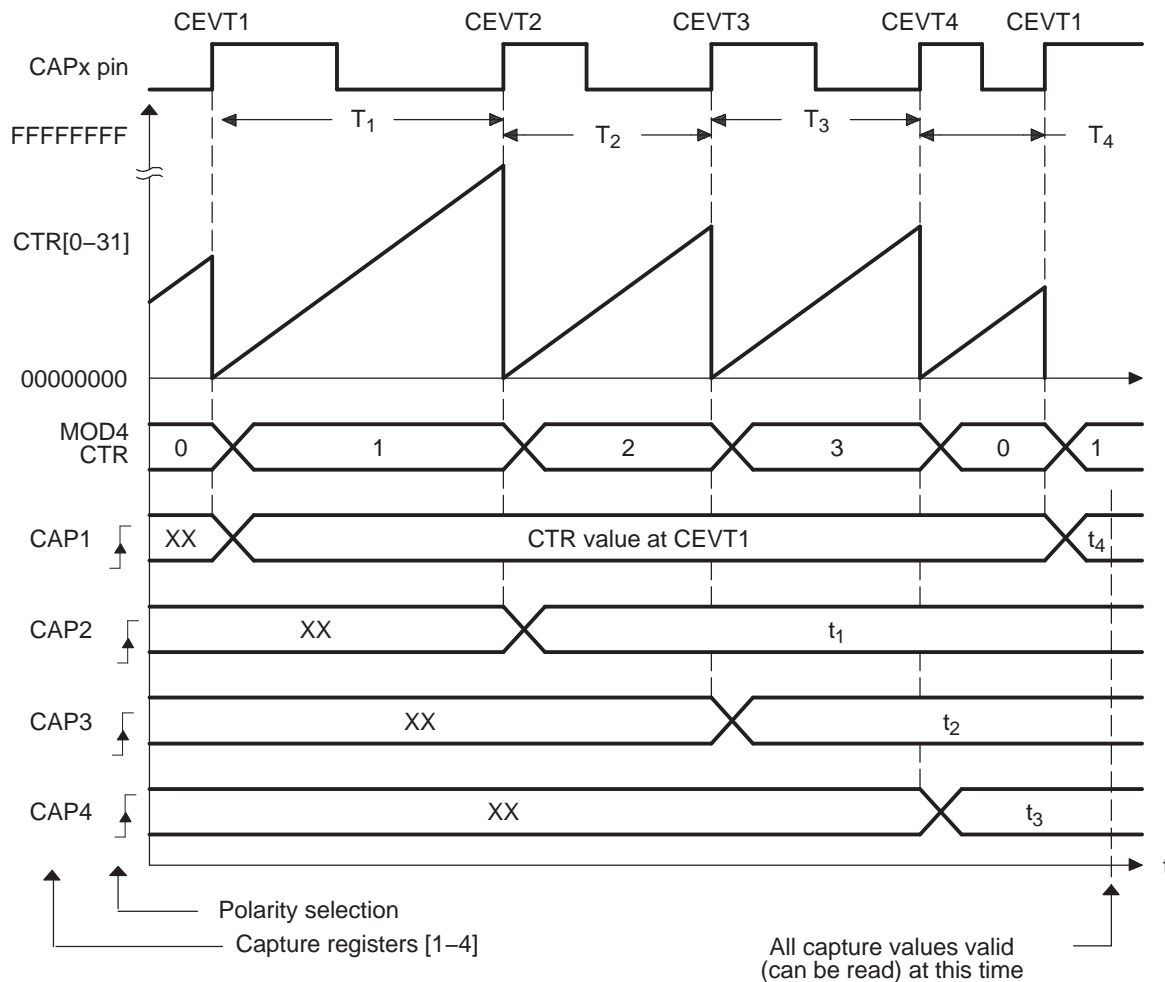

20.6.2.1 Code snippet for CAP mode Absolute Time, Rising & Falling Edge Triggers

```
// Code snippet for CAP mode Absolute Time, Rising & Falling edge triggers
// Initialization Time
//=====
// ECAP module 1 config
ECap1Regs.ECCTL1.bit.CAP1POL = EC_RISING;
ECap1Regs.ECCTL1.bit.CAP2POL = EC_FALLING;
ECap1Regs.ECCTL1.bit.CAP3POL = EC_RISING;
ECap1Regs.ECCTL1.bit.CAP4POL = EC_FALLING;
ECap1Regs.ECCTL1.bit.CTRRST1 = EC_ABS_MODE;
ECap1Regs.ECCTL1.bit.CTRRST2 = EC_ABS_MODE;
ECap1Regs.ECCTL1.bit.CTRRST3 = EC_ABS_MODE;
ECap1Regs.ECCTL1.bit.CTRRST4 = EC_ABS_MODE;
ECap1Regs.ECCTL1.bit.CAPLDEN = EC_ENABLE;
ECap1Regs.ECCTL1.bit.PRESCALE = EC_DIV1;
ECap1Regs.ECCTL2.bit.CAP_APWM = EC_CAP_MODE;
ECap1Regs.ECCTL2.bit.CONT_ONESHT = EC_CONTINUOUS;
ECap1Regs.ECCTL2.bit.SYNCO_SEL = EC_SYNCO_DIS;
ECap1Regs.ECCTL2.bit.SYNCI_EN = EC_DISABLE;
ECap1Regs.ECCTL2.bit.TSCTRSTOP = EC_RUN; // Allow TSCTR to run
// Run Time ( e.g. CEVT4 triggered ISR call)
//=====
TSt1 = ECap1Regs.CAP1; // Fetch Time-Stamp captured at t1
TSt2 = ECap1Regs.CAP2; // Fetch Time-Stamp captured at t2
TSt3 = ECap1Regs.CAP3; // Fetch Time-Stamp captured at t3
TSt4 = ECap1Regs.CAP4; // Fetch Time-Stamp captured at t4
Period1 = TSt3-TSt1; // Calculate 1st period
DutyOnTime1 = TSt2-TSt1; // Calculate On time
DutyOffTime1 = TSt3-TSt2; // Calculate Off time
```

20.6.3 Example 3 - Time Difference (Delta) Operation Rising Edge Trigger

This example Figure 20-23 shows how the eCAP module can be used to collect Delta timing data from pulse train waveforms. Here Continuous Capture mode (TSCTR counts-up without resetting, and Mod4 counter wraps around) is used. In Delta-time mode, TSCTR is Reset back to Zero on every valid event. Here Capture events are qualified as Rising edge only. On an event, TSCTR contents (that is, time-stamp) is captured first, and then TSCTR is reset to Zero. The Mod4 counter then increments to the next state. If TSCTR reaches FFFF FFFFh (that is, maximum value), before the next event, it wraps around to 0000 0000h and continues, a CINTOVF (counter overflow) Flag is set, and an Interrupt (if enabled) occurs. The advantage of Delta-time Mode is that the CAPx contents directly give timing data without the need for CPU calculations, that is, Period1 = T_1 , Period2 = T_2 , and so on. As shown in the diagram, the CEVT1 event is a good trigger point to read the timing data, T_1 , T_2 , T_3 , T_4 are all valid here.

Figure 20-23. Capture Sequence for Delta Mode Time-stamp and Rising Edge Detect

20.6.3.1 Code snippet for CAP mode Delta Time, Rising Edge Trigger

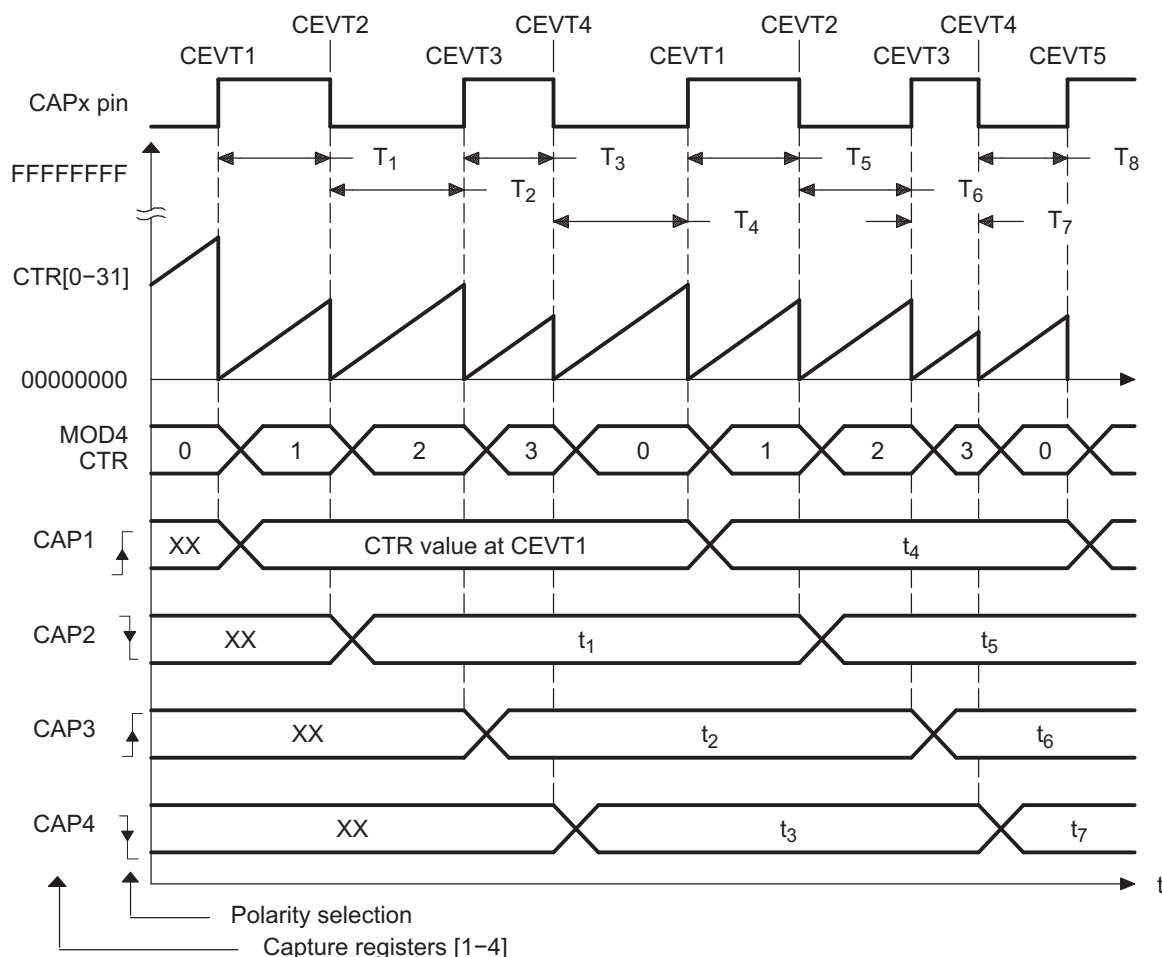

```
// Code snippet for CAP mode Delta Time, Rising edge trigger
// Initialization Time
//=====
// ECAP module 1 config
ECap1Regs.ECCTL1.bit.CAP1POL = EC_RISING;
ECap1Regs.ECCTL1.bit.CAP2POL = EC_RISING;
ECap1Regs.ECCTL1.bit.CAP3POL = EC_RISING;
ECap1Regs.ECCTL1.bit.CAP4POL = EC_RISING;
ECap1Regs.ECCTL1.bit.CTRRST1 = EC_DELTA_MODE;
ECap1Regs.ECCTL1.bit.CTRRST2 = EC_DELTA_MODE;
ECap1Regs.ECCTL1.bit.CTRRST3 = EC_DELTA_MODE;
ECap1Regs.ECCTL1.bit.CTRRST4 = EC_DELTA_MODE;
ECap1Regs.ECCTL1.bit.CAPLDEN = EC_ENABLE;
ECap1Regs.ECCTL1.bit.PRESCALE = EC_DIV1;
ECap1Regs.ECCTL2.bit.CAP_APWM = EC_CAP_MODE;
ECap1Regs.ECCTL2.bit.CONT_ONESHT = EC_CONTINUOUS;
ECap1Regs.ECCTL2.bit.SYNCO_SEL = EC_SYNCO_DIS;
ECap1Regs.ECCTL2.bit.SYNCI_EN = EC_DISABLE;
ECap1Regs.ECCTL2.bit.TSCTRSTOP = EC_RUN; // Allow TSCTR to run
// Run Time ( e.g. CEVT1 triggered ISR call)
//=====
// Note: here Time-stamp directly represents the Period value.
Period4 = ECap1Regs.CAP1; // Fetch Time-Stamp captured at T1
Period1 = ECap1Regs.CAP2; // Fetch Time-Stamp captured at T2
Period2 = ECap1Regs.CAP3; // Fetch Time-Stamp captured at T3
Period3 = ECap1Regs.CAP4; // Fetch Time-Stamp captured at T4
```

20.6.4 Example 4 - Time Difference (Delta) Operation Rising and Falling Edge Trigger

In Figure 20-24 the eCAP operating mode is almost the same as in previous section except Capture events are qualified as either Rising or Falling edge, this now gives both Period and Duty cycle information, that is, $\text{Period1} = T_1 + T_2$, $\text{Period2} = T_3 + T_4$, and so on; $\text{Duty Cycle1 (on-time \%)} = T_1 / \text{Period1} \times 100\%$, and so on; $\text{Duty Cycle1 (off-time \%)} = T_2 / \text{Period1} \times 100\%$, and so on.

During initialization, you must write to the active registers for both period and compare. This will then automatically copy the init values into the shadow values. For subsequent compare updates, during run-time, only the shadow registers must be used.

Figure 20-24. Capture Sequence for Delta Mode Time-stamp With Rising and Falling Edge Detect

20.6.4.1 Code snippet for CAP mode Delta Time, Rising and Falling Edge Triggers

```
// Code snippet for CAP mode Delta Time, Rising and Falling edge triggers
// Initialization Time
//=====
// ECAP module 1 config
ECap1Regs.ECCTL1.bit.CAP1POL = EC_RISING;
ECap1Regs.ECCTL1.bit.CAP2POL = EC_FALLING;
ECap1Regs.ECCTL1.bit.CAP3POL = EC_RISING;
ECap1Regs.ECCTL1.bit.CAP4POL = EC_FALLING;
ECap1Regs.ECCTL1.bit.CTRRST1 = EC_DELTA_MODE;
ECap1Regs.ECCTL1.bit.CTRRST2 = EC_DELTA_MODE;
ECap1Regs.ECCTL1.bit.CTRRST3 = EC_DELTA_MODE;
ECap1Regs.ECCTL1.bit.CTRRST4 = EC_DELTA_MODE;
ECap1Regs.ECCTL1.bit.CAPLDEN = EC_ENABLE;
ECap1Regs.ECCTL1.bit.PRESCALE = EC_DIV1;
ECap1Regs.ECCTL2.bit.CAP_APWM = EC_CAP_MODE;
ECap1Regs.ECCTL2.bit.CONT_ONESHT = EC_CONTINUOUS;
ECap1Regs.ECCTL2.bit.SYNCO_SEL = EC_SYNCO_DIS;
ECap1Regs.ECCTL2.bit.SYNCI_EN = EC_DISABLE;
ECap1Regs.ECCTL2.bit.TSCTRSTOP = EC_RUN; // Allow TSCTR to run
// Run Time ( e.g. CEVT1 triggered ISR call)
//=====
// Note: here Time-stamp directly represents the Duty cycle values.
DutyOnTime1 = ECap1Regs.CAP2; // Fetch Time-Stamp captured at T2
DutyOffTime1 = ECap1Regs.CAP3; // Fetch Time-Stamp captured at T3
DutyOnTime2 = ECap1Regs.CAP4; // Fetch Time-Stamp captured at T4
DutyOffTime2 = ECap1Regs.CAP1; // Fetch Time-Stamp captured at T1
Period1 = DutyOnTime1 + DutyOffTime1;
Period2 = DutyOnTime2 + DutyOffTime2;
```

20.7 Application of the APWM Mode

In this example, the eCAP module is configured to operate as a PWM generator. Here a very simple single channel PWM waveform is generated from output pin APWMx. The PWM polarity is active high, which means that the compare value (CAP2 reg is now a compare register) represents the on-time (high level) of the period. Alternatively, if the APWMPOL bit is configured for active low, then the compare value represents the off-time. Note here values are in hexadecimal (h) notation.

20.7.1 Simple PWM Generation (Independent Channel/s)

Figure 20-25. PWM Waveform Details of APWM Mode Operation

Example 20-1. Code Snippet for APWM Mode

```
// Code snippet for APWM mode Example 1
// Initialization Time
//=====
// ECAP module 1 config
ECap1Regs.CAP1 = 0x1000; // Set period value
ECap1Regs.CTRPHS = 0x0; // make phase zero
ECap1Regs.ECCTL2.bit.CAP_APWM = EC_APWM_MODE;
ECap1Regs.ECCTL2.bit.APWMPOL = EC_ACTV_HI; // Active high
ECap1Regs.ECCTL2.bit.SYNCI_EN = EC_DISABLE; // Synch not used
ECap1Regs.ECCTL2.bit.SYNCO_SEL = EC_SYNCO_DIS; // Synch not used
ECap1Regs.ECCTL2.bit.TSCTRSTOP = EC_RUN; // Allow TSCTR to run
// Run Time (Instant 1, e.g. ISR call)
//=====
ECap1Regs.CAP2 = 0x300; // Set Duty cycle i.e. compare value
// Run Time (Instant 2, e.g. another ISR call)
//=====
ECap1Regs.CAP2 = 0x500; // Set Duty cycle i.e. compare value
```

Enhanced Quadrature Encoder Pulse (eQEP) Module

The enhanced quadrature encoder pulse (eQEP) module is used for direct interface with a linear or rotary incremental encoder to get position, direction, and speed information from a rotating machine for use in a high-performance motion and position-control system. This microcontroller implements 2 instances of the eQEP module.

| Topic | Page |
|--|------------|

Quadrature encoders from different manufacturers come with two forms of index pulse (gated index pulse or ungated index pulse) as shown in Figure 21-3. A nonstandard form of index pulse is ungated. In the ungated configuration, the index edges are not necessarily coincident with A and B signals. The gated index pulse is aligned to any of the four quadrature edges and width of the index pulse and can be equal to a quarter, half, or full period of the quadrature signal.

Figure 21-3. Index Pulse Example

Some typical applications of shaft encoders include robotics and even computer input in the form of a mouse. Inside your mouse you can see where the mouse ball spins a pair of axles (a left/right, and an up/down axle). These axles are connected to optical shaft encoders that effectively tell the computer how fast and in what direction the mouse is moving.

General Issues: Estimating velocity from a digital position sensor is a cost-effective strategy in motor control. Two different first order approximations for velocity may be written as:

$$v(k) \approx \frac{x(k) - x(k-1)}{T} = \frac{\Delta X}{T} \quad (28)$$

$$v(k) \approx \frac{X}{t(k) - t(k-1)} = \frac{X}{\Delta T} \quad (29)$$

where

$v(k)$: Velocity at time instant k

$x(k)$: Position at time instant k

$x(k-1)$: Position at time instant $k-1$

T : Fixed unit time or inverse of velocity calculation rate

ΔX : Incremental position movement in unit time

$t(k)$: Time instant " k "

$t(k-1)$: Time instant " $k-1$ "

X : Fixed unit position

ΔT : Incremental time elapsed for unit position movement.

Equation 28 is the conventional approach to velocity estimation and it requires a time base to provide unit time event for velocity calculation. Unit time is basically the inverse of the velocity calculation rate.

The encoder count (position) is read once during each unit time event. The quantity $[x(k) - x(k-1)]$ is formed by subtracting the previous reading from the current reading. Then the velocity estimate is computed by multiplying by the known constant $1/T$ (where T is the constant time between unit time events and is known in advance).

Estimation based on Equation 28 has an inherent accuracy limit directly related to the resolution of the position sensor and the unit time period T . For example, consider a 500-line per revolution quadrature encoder with a velocity calculation rate of 400 Hz. When used for position the quadrature encoder gives a four-fold increase in resolution, in this case, 2000 counts per revolution. The minimum rotation that can be detected is therefore 0.0005 revolutions, which gives a velocity resolution of 12 rpm when sampled at 400 Hz. While this resolution may be satisfactory at moderate or high speeds, for example, 1% error at 1200 rpm, it would clearly prove inadequate at low speeds. In fact, at speeds below 12 rpm, the speed estimate would erroneously be zero much of the time.

At low speed, Equation 29 provides a more accurate approach. It requires a position sensor that outputs a fixed interval pulse train, such as the aforementioned quadrature encoder. The width of each pulse is defined by motor speed for a given sensor resolution. Equation 29 can be used to calculate motor speed by measuring the elapsed time between successive quadrature pulse edges. However, this method suffers from the opposite limitation, as does Equation 28. A combination of relatively large motor speeds and high sensor resolution makes the time interval ΔT small, and thus more greatly influenced by the timer resolution. This can introduce considerable error into high-speed estimates.

For systems with a large speed range (that is, speed estimation is needed at both low and high speeds), one approach is to use Equation 29 at low speed and have the DSP software switch over to Equation 28 when the motor speed rises above some specified threshold.

21.2 Description

This section provides the eQEP inputs, memory map, and functional description.

21.2.1 EQEP Inputs

The eQEP inputs include two pins for quadrature-clock mode or direction-count mode, an index (or 0 marker), and a strobe input.

- **QEPA/XCLK and QEPB/XDIR**

These two pins can be used in quadrature-clock mode or direction-count mode.

- **Quadrature-clock Mode**

The eQEP encoders provide two square wave signals (A and B) 90 electrical degrees out of phase whose phase relationship is used to determine the direction of rotation of the input shaft and number of eQEP pulses from the index position to derive the relative position information. For forward or clockwise rotation, QEPA signal leads QEPB signal and vice versa. The quadrature decoder uses these two inputs to generate quadrature-clock and direction signals.

- **Direction-count Mode**

In direction-count mode, direction and clock signals are provided directly from the external source. Some position encoders have this type of output instead of quadrature output. The QEPA pin provides the clock input and the QEPB pin provides the direction input.

- **eQEPI: Index or Zero Marker**

The eQEP encoder uses an index signal to assign an absolute start position from which position information is incrementally encoded using quadrature pulses. This pin is connected to the index output of the eQEP encoder to optionally reset the position counter for each revolution. This signal can be used to initialize or latch the position counter on the occurrence of a desired event on the index pin.

- **QEPS: Strobe Input**

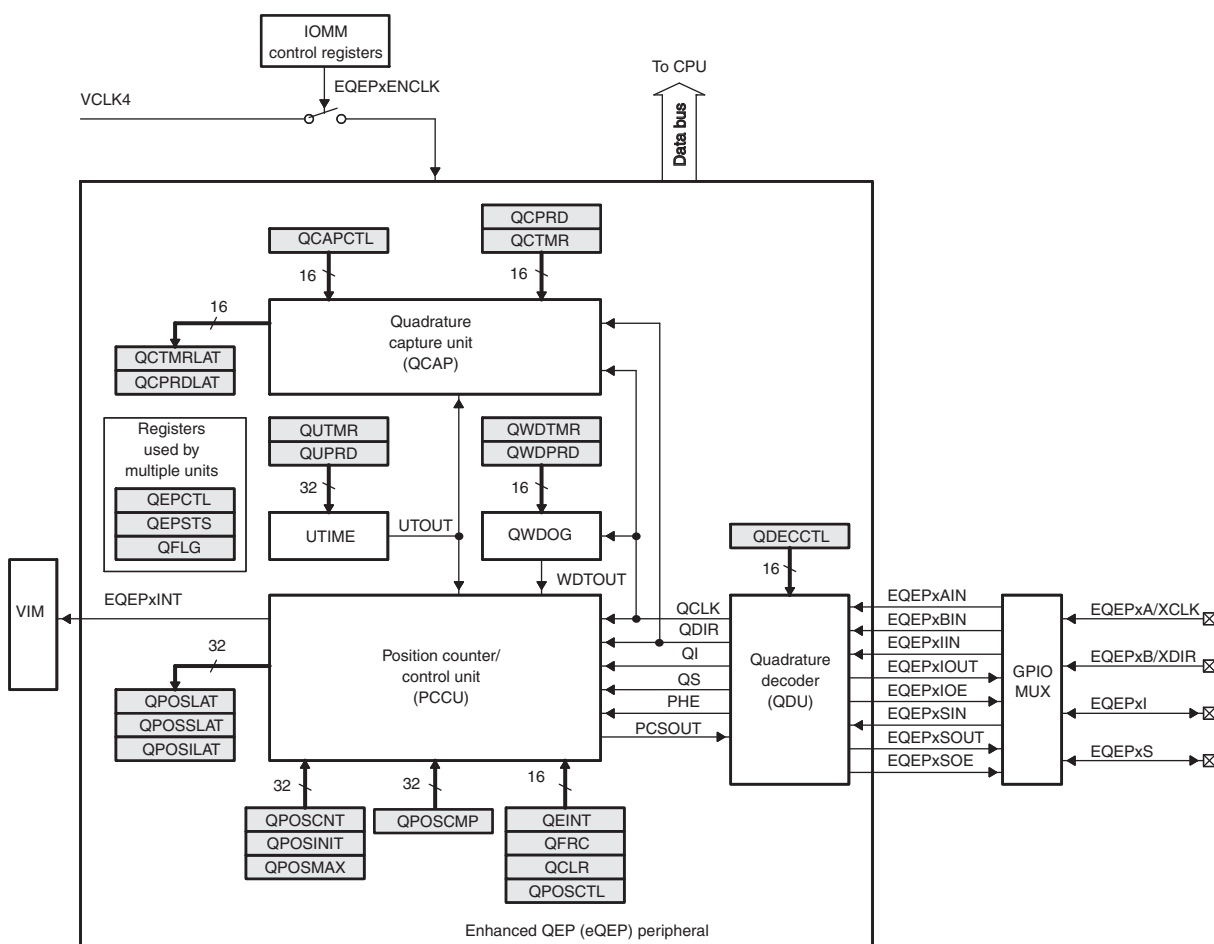

This general-purpose strobe signal can initialize or latch the position counter on the occurrence of a desired event on the strobe pin. This signal is typically connected to a sensor or limit switch to notify that the motor has reached a defined position.

21.2.2 Functional Description

The eQEP peripheral contains the following major functional units (as shown in Figure 21-4):

- Programmable input qualification for each pin (part of the GPIO MUX)
- Quadrature decoder unit (QDU)
- Position counter and control unit for position measurement (PCCU)
- Quadrature edge-capture unit for low-speed measurement (QCAP)
- Unit time base for speed/frequency measurement (UTIME)
- Watchdog timer for detecting stalls (QWDOG)

Figure 21-4. Functional Block Diagram of the eQEP Peripheral

21.2.3 eQEP Memory Map

Table 21-1 lists the registers with their memory locations, sizes, and reset values.

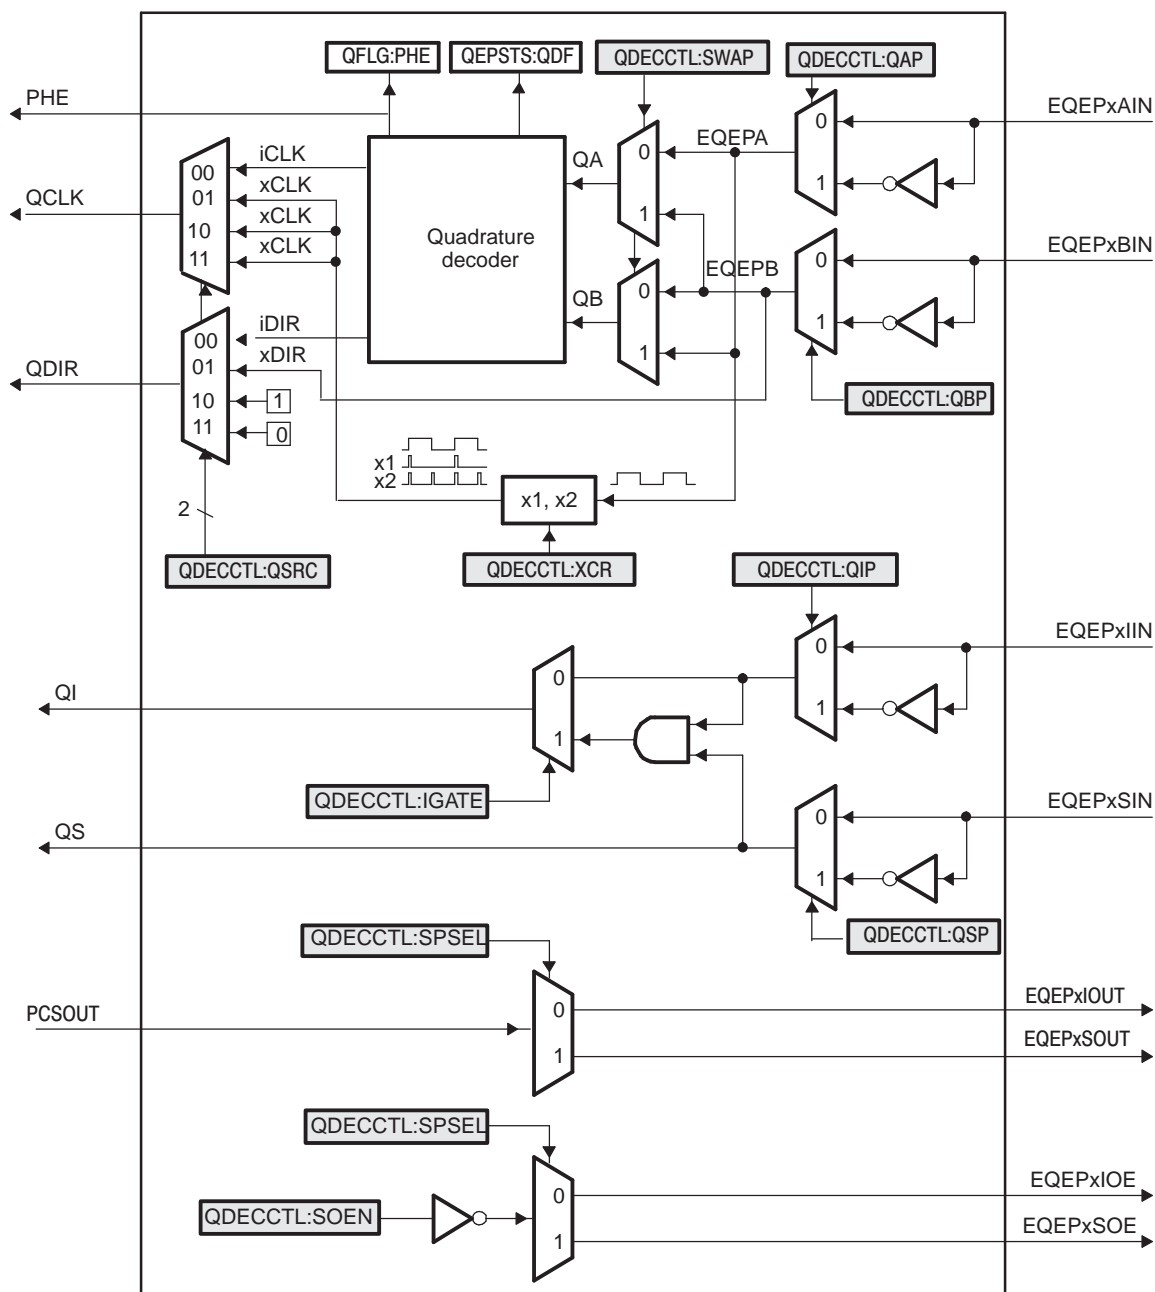

Table 21-1. EQEP Memory Map

| Name | Address Offset | Size(x16)/ #shadow | Reset | Register Description |
|----------|----------------|--------------------|------------|--|
| QPOSCNT | 0x00 | 2/0 | 0x00000000 | eQEP Position Counter |

21.3 Quadrature Decoder Unit (QDU)

Figure 21-5 shows a functional block diagram of the QDU.

Figure 21-5. Functional Block Diagram of Decoder Unit

21.3.1 Position Counter Input Modes

Clock and direction input to position counter is selected using QDECCTL[QSRC] bits, based on interface input requirement as follows:

- Quadrature-count mode
- Direction-count mode
- UP-count mode
- DOWN-count mode

21.3.1.1 Quadrature Count Mode

The quadrature decoder generates the direction and clock to the position counter in quadrature count mode.

Direction Decoding— The direction decoding logic of the eQEP circuit determines which one of the sequences (QEPA, QEPB) is the leading sequence and accordingly updates the direction information in QEPSTS[QDF] bit. [Table 21-2](#) and [Figure 21-6](#) show the direction decoding logic in truth table and state machine form. Both edges of the QEPA and QEPB signals are sensed to generate count pulses for the position counter. Therefore, the frequency of the clock generated by the eQEP logic is four times that of each input sequence. [Figure 21-7](#) shows the direction decoding and clock generation from the eQEP input signals.

Phase Error Flag— In normal operating conditions, quadrature inputs QEPA and QEPB will be 90 degrees out of phase. The phase error flag (PHE) is set in the QFLG register when edge transition is detected simultaneously on the QEPA and QEPB signals to optionally generate interrupts. State transitions marked by dashed lines in [Figure 21-6](#) are invalid transitions that generate a phase error.

Count Multiplication— The eQEP position counter provides 4x times the resolution of an input clock by generating a quadrature-clock (QCLK) on the rising/falling edges of both eQEP input clocks (QEPA and QEPB) as shown in [Figure 21-7](#).

Reverse Count— In normal quadrature count operation, QEPA input is fed to the QA input of the quadrature decoder and the QEPB input is fed to the QB input of the quadrature decoder. Reverse counting is enabled by setting the SWAP bit in the QDECCTL register. This will swap the input to the quadrature decoder thereby reversing the counting direction.

Table 21-2. Quadrature Decoder Truth Table

| Previous Edge | Present Edge | QDIR | QPOSCNT |
|---------------|--------------|--------|------------------------|
| QA↑ | QB↑ | UP | Increment |
| | QB↓ | DOWN | Decrement |
| | QA↓ | TOGGLE | Increment or Decrement |
| QA↓ | QB↓ | UP | Increment |
| | QB↑ | DOWN | Decrement |
| | QA↑ | TOGGLE | Increment or Decrement |
| QB↑ | QA↑ | DOWN | Increment |
| | QA↓ | UP | Decrement |
| | QB↓ | TOGGLE | Increment or Decrement |
| QB↓ | QA↓ | DOWN | Increment |
| | QA↑ | UP | Decrement |
| | QB↑ | TOGGLE | Increment or Decrement |

Figure 21-6. Quadrature Decoder State Machine

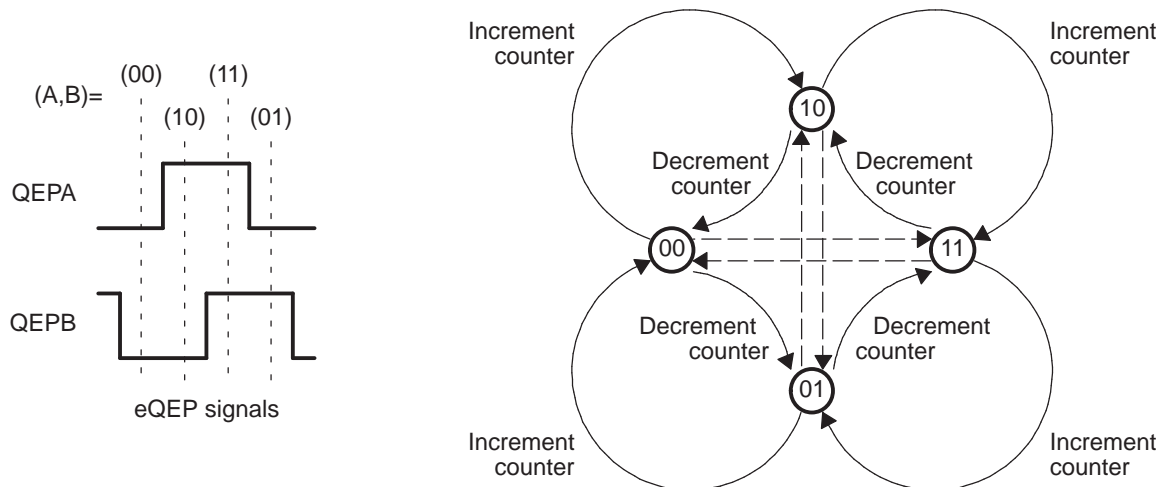

Figure 21-7. Quadrature-clock and Direction Decoding

21.3.1.2 Direction-Count Mode

Some position encoders provide direction and clock outputs, instead of quadrature outputs. In such cases, direction-count mode can be used. QEPA input will provide the clock for position counter and the QEPB input will have the direction information. The position counter is incremented on every rising edge of a QEPA input when the direction input is high and decremented when the direction input is low.

21.3.1.3 Up-Count Mode

The counter direction signal is hard-wired for up count and the position counter is used to measure the frequency of the QEPA input. Setting of the QDECCTL[XCR] bit enables clock generation to the position counter on both edges of the QEPA input, thereby increasing the measurement resolution by 2x factor.

21.3.1.4 Down-Count Mode

The counter direction signal is hardwired for a down count and the position counter is used to measure the frequency of the QEPA input. Setting of the QDECCTL[XCR] bit enables clock generation to the position counter on both edges of a QEPA input, thereby increasing the measurement resolution by 2x factor.

21.3.2 eQEP Input Polarity Selection

Each eQEP input can be inverted using QDECCTL[8:5] control bits. As an example, setting of QDECCTL[QIP] bit will invert the index input.

21.3.3 Position-Compare Sync Output

The enhanced eQEP peripheral includes a position-compare unit that is used to generate the position-compare sync signal on compare match between the position counter register (QPOSCNT) and the position-compare register (QPOSCMP). This sync signal can be output using an index pin or strobe pin of the EQEP peripheral.

Setting the QDECCTL[SOEN] bit enables the position-compare sync output and the QDECCTL[SPSEL] bit selects either an eQEP index pin or an eQEP strobe pin.

21.4 Position Counter and Control Unit (PCCU)

The position counter and control unit provides two configuration registers (QEPCTL and QPOSCTL) for setting up position counter operational modes, position counter initialization/latch modes and position-compare logic for sync signal generation.

21.4.1 Position Counter Operating Modes

Position counter data may be captured in different manners. In some systems, the position counter is accumulated continuously for multiple revolutions and the position counter value provides the position information with respect to the known reference. An example of this is the quadrature encoder mounted on the motor controlling the print head in the printer. Here the position counter is reset by moving the print head to the home position and then position counter provides absolute position information with respect to home position.

In other systems, the position counter is reset on every revolution using index pulse and position counter provides rotor angle with respect to index pulse position.

Position counter can be configured to operate in following four modes

- Position Counter Reset on Index Event
- Position Counter Reset on Maximum Position
- Position Counter Reset on the first Index Event
- Position Counter Reset on Unit Time Out Event (Frequency Measurement)

In all the above operating modes, position counter is reset to 0 on overflow and to QPOS MAX register value on underflow. Overflow occurs when the position counter counts up after QPOS MAX value. Underflow occurs when position counter counts down after "0". Interrupt flag is set to indicate overflow/underflow in QFLG register.

21.4.1.1 Position Counter Reset on Index Event (QEPCTL[PCRM] = 00)

If the index event occurs during the forward movement, then position counter is reset to 0 on the next eQEP clock. If the index event occurs during the reverse movement, then the position counter is reset to the value in the QPOSMAX register on the next eQEP clock.

First index marker is defined as the quadrature edge following the first index edge. The eQEP peripheral records the occurrence of the first index marker (QEPSTS[FIMF]) and direction on the first index event marker (QEPSTS[FIDF]) in QEPSTS registers, it also remembers the quadrature edge on the first index marker so that same relative quadrature transition is used for index event reset operation.

For example, if the first reset operation occurs on the falling edge of QEPB during the forward direction, then all the subsequent reset must be aligned with the falling edge of QEPB for the forward rotation and on the rising edge of QEPB for the reverse rotation as shown in Figure 21-8.

The position-counter value is latched to the QPOSILAT register and direction information is recorded in the QEPSTS[QDLF] bit on every index event marker. The position-counter error flag (QEPSTS[PCEF]) and error interrupt flag (QFLG[PCE]) are set if the latched value is not equal to 0 or QPOSMAX. The position-counter error flag (QEPSTS[PCEF]) is updated on every index event marker and an interrupt flag (QFLG[PCE]) will be set on error that can be cleared only through software.

The index event latch configuration QEPCTL[IEL] bits are ignored in this mode and position counter error flag/interrupt flag are generated only in index event reset mode.

Figure 21-8. Position Counter Reset by Index Pulse for 1000 Line Encoder (QPOSMAX = 3999 or 0xF9F)

21.4.1.2 Position Counter Reset on Maximum Position (QEPCTL[PCRM] = 01)

If the position counter is equal to QPOS MAX, then the position counter is reset to 0 on the next eQEP clock for forward movement and position counter overflow flag is set. If the position counter is equal to ZERO, then the position counter is reset to QPOS MAX on the next QEP clock for reverse movement and position counter underflow flag is set. Figure 21-9 shows the position counter reset operation in this mode.

First index marker is defined as the quadrature edge following the first index edge. The eQEP peripheral records the occurrence of the first index marker (QEPSTS[FIMF]) and direction on the first index event marker (QEPSTS[FIDF]) in the QEPSTS registers; it also remembers the quadrature edge on the first index marker so that the same relative quadrature transition is used for the software index marker (QEPCTL[IEL]=11).

Figure 21-9. Position Counter Underflow/Overflow (QPOS MAX = 4)

21.4.1.3 Position Counter Reset on the First Index Event (QEPCTL[PCRM] = 10)

If the index event occurs during forward movement, then the position counter is reset to 0 on the next eQEP clock. If the index event occurs during the reverse movement, then the position counter is reset to the value in the QPOSMAX register on the next eQEP clock. Note that this is done only on the first occurrence and subsequently the position counter value is not reset on an index event; rather, it is reset based on maximum position as described in [Section 21.4.1.2](#).

First index marker is defined as the quadrature edge following the first index edge. The eQEP peripheral records the occurrence of the first index marker (QEPSTS[FIMF]) and direction on the first index event marker (QEPSTS[FIDF]) in QEPSTS registers, it also remembers the quadrature edge on the first index marker so that same relative quadrature transition is used for software index marker (QEPCTL[IEL]=11).

21.4.1.4 Position Counter Reset on Unit Time out Event (QEPCTL[PCRM] = 11)

In this mode, the QPOSCNT value is latched to the QPOSLAT register and then the QPOSCNT is reset (to 0 or QPOSMAX, depending on the direction mode selected by QDECCTL[QSRC] bits on a unit time event). This is useful for frequency measurement.

21.4.2 Position Counter Latch

The eQEP index and strobe input can be configured to latch the position counter (QPOSCNT) into QPOSILAT and QPOSSLAT, respectively, on occurrence of a definite event on these pins.

21.4.2.1 Index Event Latch

In some applications, it may not be desirable to reset the position counter on every index event and instead it may be required to operate the position counter in full 32-bit mode (QEPCTL[PCRM] = 01 and QEPCTL[PCRM] = 10 modes).

In such cases, the eQEP position counter can be configured to latch on the following events and direction information is recorded in the QEPSTS[QDLF] bit on every index event marker.

- Latch on Rising edge (QEPCTL[IEL]=01)
- Latch on Falling edge (QEPCTL[IEL]=10)
- Latch on Index Event Marker (QEPCTL[IEL]=11)

This is particularly useful as an error checking mechanism to check if the position counter accumulated the correct number of counts between index events. As an example, the 1000-line encoder must count 4000 times when moving in the same direction between the index events.

The index event latch interrupt flag (QFLG[IEL]) is set when the position counter is latched to the QPOSILAT register. The index event latch configuration bits (QEPCTZ[IEL]) are ignored when QEPCTL[PCRM] = 00.

Latch on Rising Edge (QEPCTL[IEL]=01)— The position counter value (QPOSCNT) is latched to the QPOSILAT register on every rising edge of an index input.

Latch on Falling Edge (QEPCTL[IEL] = 10)— The position counter value (QPOSCNT) is latched to the QPOSILAT register on every falling edge of index input.

Latch on Index Event Marker/Software Index Marker (QEPCTL[IEL] = 11)— The first index marker is defined as the quadrature edge following the first index edge. The eQEP peripheral records the occurrence of the first index marker (QEPSTS[FIMF]) and direction on the first index event marker (QEPSTS[FIDF]) in the QEPSTS registers. It also remembers the quadrature edge on the first index marker so that same relative quadrature transition is used for latching the position counter (QEPCTL[IEL]=11).

[Figure 21-10](#) shows the position counter latch using an index event marker.

Figure 21-10. Software Index Marker for 1000-line Encoder (QEPCTL[IEL] = 1)

21.4.2.2 Strobe Event Latch

The position-counter value is latched to the QPOSSLAT register on the rising edge of the strobe input by clearing the QEPCTL[SEL] bit.

If the QEPCTL[SEL] bit is set, then the position counter value is latched to the QPOSSLAT register on the rising edge of the strobe input for forward direction and on the falling edge of the strobe input for reverse direction as shown in [Figure 21-11](#).

The strobe event latch interrupt flag (QFLG[SEL]) is set when the position counter is latched to the QPOSSLAT register.

Figure 21-11. Strobe Event Latch (QEPCTL[SEL] = 1)

21.4.3 Position Counter Initialization

The position counter can be initialized using following events:

- Index event
- Strobe event
- Software initialization

Index Event Initialization (IEI)— The QEPI index input can be used to trigger the initialization of the position counter at the rising or falling edge of the index input. If the QEPCTL[IEI] bits are 10, then the position counter (QPOSCNT) is initialized with a value in the QPOSINIT register on the rising edge of index input. Conversely, if the QEPCTL[IEI] bits are 11, initialization will be on the falling edge of the index input.

Strobe Event Initialization (SEI)— If the QEPCTL[SEI] bits are 10, then the position counter is initialized with a value in the QPOSINIT register on the rising edge of strobe input.

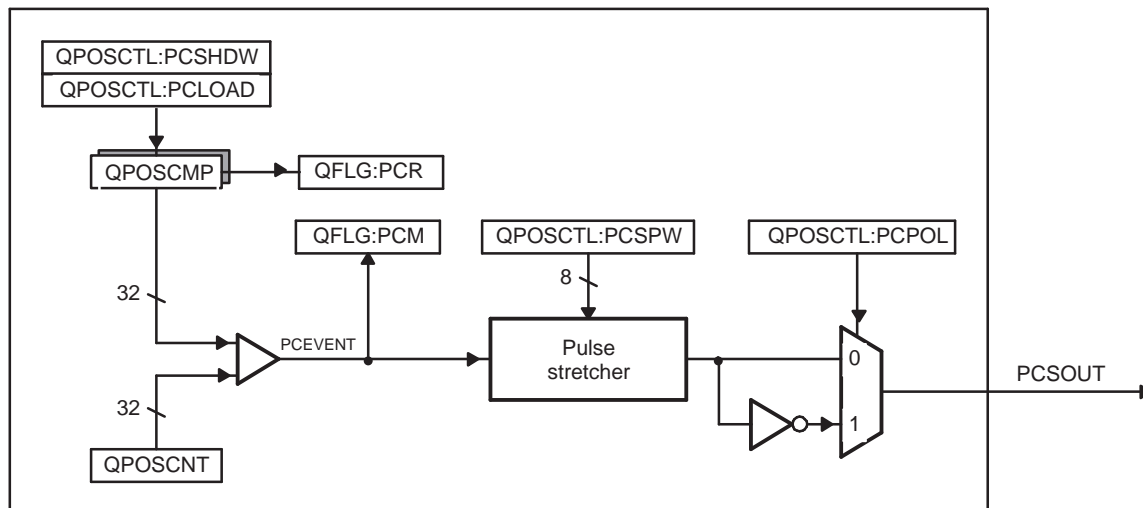

If QEPCTL[SEL] bits are 11, then the position counter is initialized with a value in the QPOSINIT register on the rising edge of strobe input for forward direction and on the falling edge of strobe input for reverse direction.

Software Initialization (SWI)— The position counter can be initialized in software by writing a 1 to the QEPCTL[SWI] bit. This bit is not automatically cleared. While the bit is still set, if a 1 is written to it again, the position counter will be re-initialized.

21.4.4 eQEP Position-compare Unit

The eQEP peripheral includes a position-compare unit that is used to generate a sync output and/or interrupt on a position-compare match. Figure 21-12 shows a diagram. The position-compare (QPOSCMP) register is shadowed and shadow mode can be enabled or disabled using the QPOSCTL[PSSHDW] bit. If the shadow mode is not enabled, the CPU writes directly to the active position compare register.

Figure 21-12. eQEP Position-compare Unit

In shadow mode, you can configure the position-compare unit (QPOSCTL[PCLOAD]) to load the shadow register value into the active register on the following events and to generate the position-compare ready (QFLG[PCR]) interrupt after loading.

- Load on compare match
- Load on position-counter zero event

The position-compare match (QFLG[PCM]) is set when the position-counter value (QPOSCNT) matches with the active position-compare register (QPOSCMP) and the position-compare sync output of the programmable pulse width is generated on compare match to trigger an external device.

For example, if QPOSCMP = 2, the position-compare unit generates a position-compare event on 1 to 2 transitions of the eQEP position counter for forward counting direction and on 3 to 2 transitions of the eQEP position counter for reverse counting direction (see [Figure 21-13](#)).

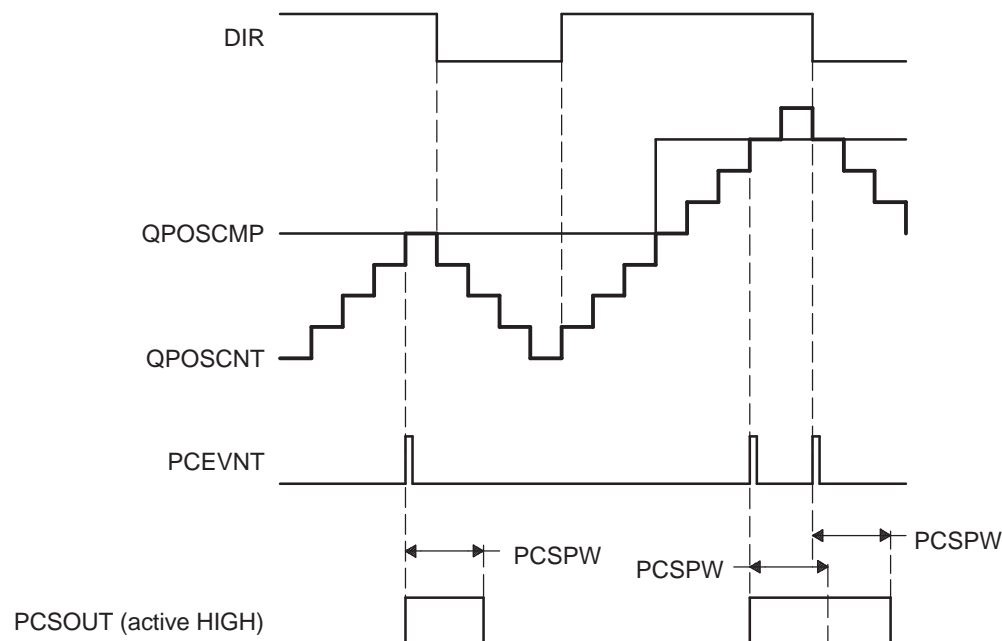

[Section 21.9.14](#) shows the layout of the eQEP Position-Compare Control Register (QPOSCTL) and describes the QPOSCTL bit fields.

Figure 21-13. eQEP Position-compare Event Generation Points

The pulse stretcher logic in the position-compare unit generates a programmable position-compare sync pulse output on the position-compare match. In the event of a new position-compare match while a previous position-compare pulse is still active, then the pulse stretcher generates a pulse of specified duration from the new position-compare event as shown in [Figure 21-14](#).

Figure 21-14. eQEP Position-compare Sync Output Pulse Stretcher

21.5 eQEP Edge Capture Unit

The eQEP peripheral includes an integrated edge capture unit to measure the elapsed time between the unit position events as shown in [Figure 21-15](#). This feature is typically used for low speed measurement using the following equation:

$$v(k) = \frac{X}{t(k) - t(k - 1)} = \frac{X}{\Delta T} \quad (30)$$

where,

- X - Unit position is defined by integer multiple of quadrature edges (see [Figure 21-16](#))
- ΔT - Elapsed time between unit position events
- $v(k)$ - Velocity at time instant "k"

The eQEP capture timer (QCTMR) runs from prescaled VCLK4 and the prescaler is programmed by the QCAPCTL[CCPS] bits. The capture timer (QCTMR) value is latched into the capture period register (QCPRD) on every unit position event and then the capture timer is reset, a flag is set in QEPSTS:UPEVNT to indicate that new value is latched into the QCPRD register. Software can check this status flag before reading the period register for low speed measurement and clear the flag by writing 1.

Time measurement (ΔT) between unit position events will be correct if the following conditions are met:

- No more than 65,535 counts have occurred between unit position events.
- No direction change between unit position events.

The capture unit sets the eQEP overflow error flag (QEPSTS[COEF]) in the event of capture timer overflow between unit position events. If a direction change occurs between the unit position events, then an error flag is set in the status register (QEPSTS[CDEF]).

Capture Timer (QCTMR) and Capture period register (QCPRD) can be configured to latch on following events.

- CPU read of QPOSCNT register
- Unit time-out event

If the QEPCTL[QCLM] bit is cleared, then the capture timer and capture period values are latched into the QCTMRLAT and QCPRDLAT registers, respectively, when the CPU reads the position counter (QPOSCNT).

If the QEPCTL[QCLM] bit is set, then the position counter, capture timer, and capture period values are latched into the QPOSLAT, QCTMRLAT and QCPRDLAT registers, respectively, on unit time out.

[Figure 21-17](#) shows the capture unit operation along with the position counter.

Figure 21-15. eQEP Edge Capture Unit

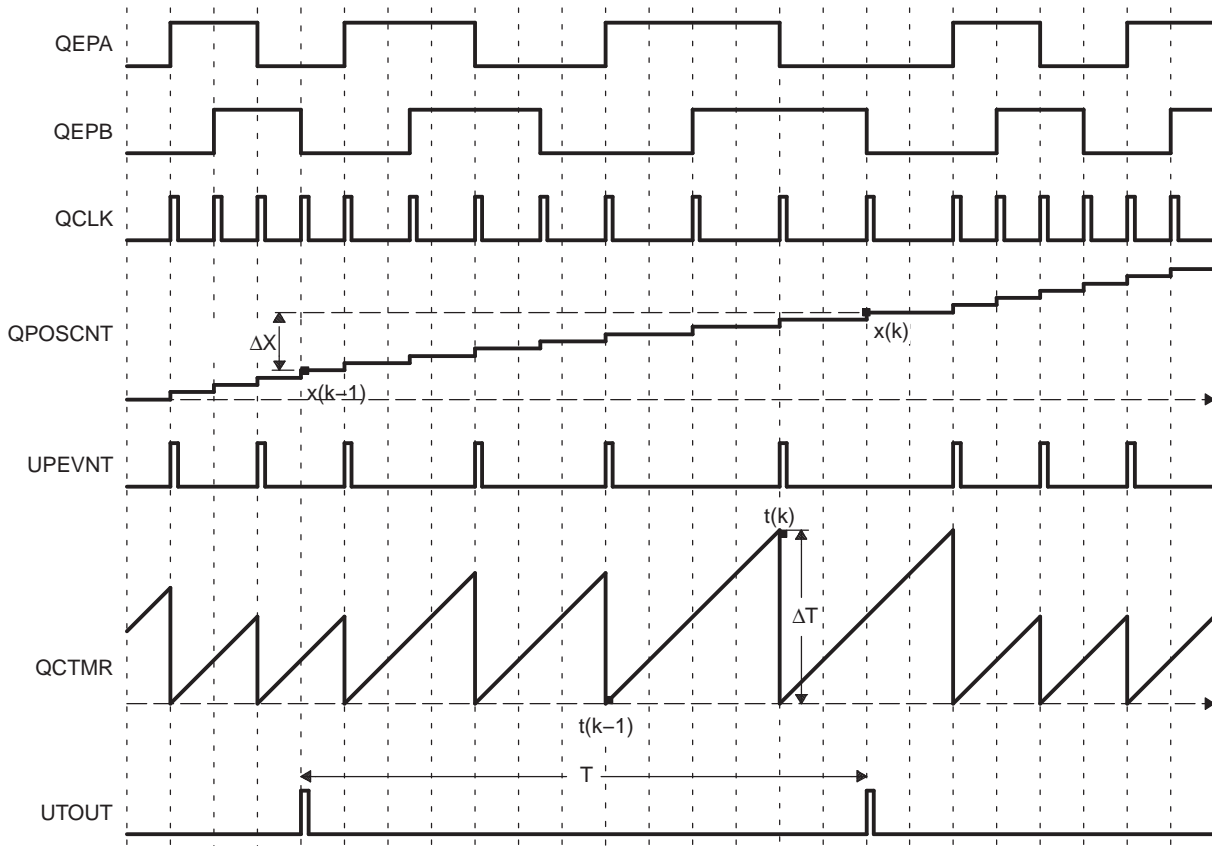

NOTE: The QCAPCTL[UPPS] prescaler should not be modified dynamically (such as switching the unit event prescaler from QCLK/4 to QCLK/8). Doing so may result in undefined behavior. The QCAPCTL[CCPS] prescaler can be modified dynamically (such as switching CAPCLK prescaling mode from SYSCLK/4 to SYSCLK/8) only after the capture unit is disabled.

Figure 21-16. Unit Position Event for Low Speed Measurement (QCAPCTL[UPPS] = 0010)

N = Number of quadrature periods selected using QCAPCTL[UPPS] bits

Figure 21-17. eQEP Edge Capture Unit - Timing Details

Velocity Calculation Equations:

$$v(k) = \frac{x(k) - x(k-1)}{T} = \frac{\Delta X}{T} \quad (31)$$

where

$v(k)$: Velocity at time instant k

$x(k)$: Position at time instant k

$x(k-1)$: Position at time instant $k-1$

T : Fixed unit time or inverse of velocity calculation rate

ΔX : Incremental position movement in unit time

X : Fixed unit position

ΔT : Incremental time elapsed for unit position movement

$t(k)$: Time instant " k "

$t(k-1)$: Time instant " $k-1$ "

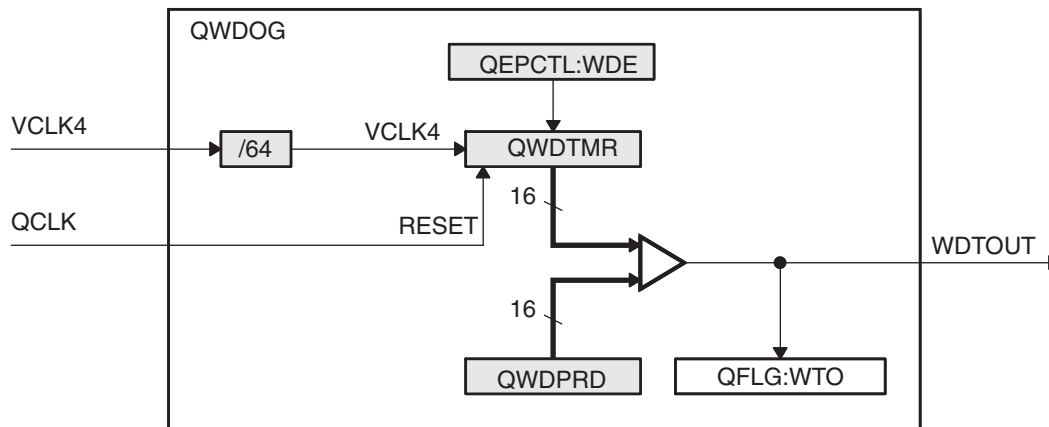

Unit time (T) and unit period(X) are configured using the QUPRD and QCAPCTL[UPPS] registers. Incremental position output and incremental time output is available in the QPOSLAT and QCPRDLAT registers.

| Parameter | Relevant Register to Configure or Read the Information |
|------------|---|
| T | Unit Period Register (QUPRD) |
| ΔX | Incremental Position = QPOSAT(k) - QPOSAT(K-1) |
| X | Fixed unit position defined by sensor resolution and ZCAPCTL[Upps] bits |
| ΔT | Capture Period Latch (QCPRDLAT) |

21.6 eQEP Watchdog

The eQEP peripheral contains a 16-bit watchdog timer that monitors the quadrature-clock to indicate proper operation of the motion-control system. The eQEP watchdog timer is clocked from VCLK4/64 and the quadrature clock event (pulse) resets the watchdog timer. If no quadrature-clock event is detected until a period match ($QWDPRD = QWDTMR$), then the watchdog timer will time out and the watchdog interrupt flag will be set (QFLG[WTO]). The time-out value is programmable through the watchdog period register (QWDPRD).

Figure 21-18. eQEP Watchdog Timer

21.7 Unit Timer Base

The eQEP peripheral includes a 32-bit timer (QUTMR) that is clocked by VCLK4 to generate periodic interrupts for velocity calculations. The unit time out interrupt is set (QFLG[UTO]) when the unit timer (QUTMR) matches the unit period register (QUPRD).

The eQEP peripheral can be configured to latch the position counter, capture timer, and capture period values on a unit time out event so that latched values are used for velocity calculation as described in [Section 21.5](#).

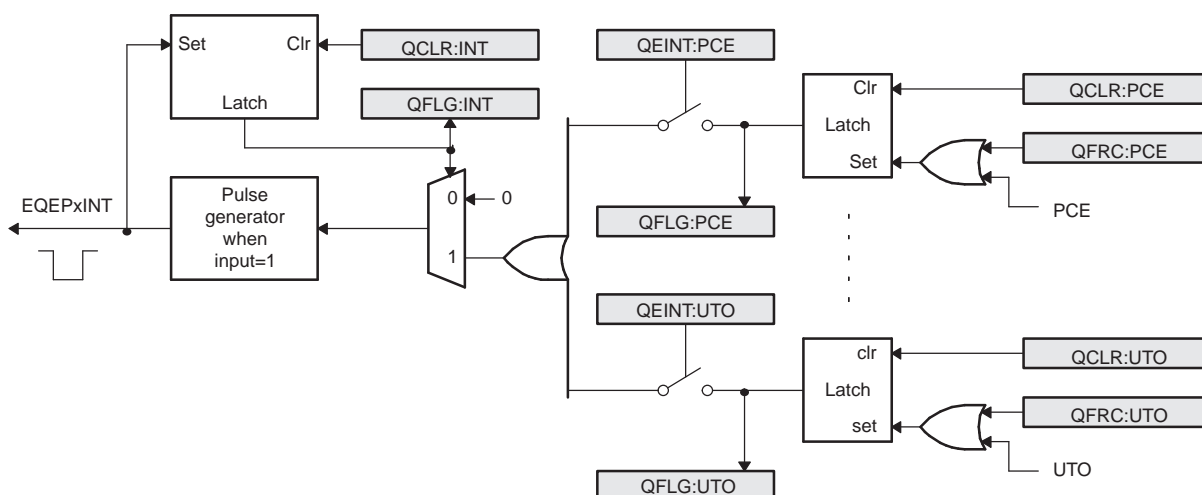

Figure 21-19. eQEP Unit Time Base

21.8 eQEP Interrupt Structure

Figure 21-20 shows how the interrupt mechanism works in the EQEP module.

Figure 21-20. EQEP Interrupt Generation

Eleven interrupt events (PCE, PHE, QDC, WTO, PCU, PCO, PCR, PCM, SEL, IEL and UTO) can be generated. The interrupt control register (QEINT) is used to enable/disable individual interrupt event sources. The interrupt flag register (QFLG) indicates if any interrupt event has been latched and contains the global interrupt flag bit (INT). An interrupt pulse is generated only to the PIE if any of the interrupt events is enabled, the flag bit is 1 and the INT flag bit is 0. The interrupt service routine will need to clear the global interrupt flag bit and the serviced event, via the interrupt clear register (QCLR), before any other interrupt pulses are generated. You can force an interrupt event by way of the interrupt force register (QFRC), which is useful for test purposes.

21.9 EQEP Registers

Table 21-3 lists the memory-mapped registers for the EQEP. All register offset addresses not listed in Table 21-3 should be considered as reserved locations and the register contents should not be modified. The base address for the control registers is FCF7 9900h for eQEP1 and FCF7 9A00h for eQEP2.

Table 21-3. EQEP Registers

| Offset | Acronym | Register Name | Section |
|--------|----------|---|---------------------------------|
| 0h | QPOSCNT | eQEP Position Counter Register | Section 21.9.1 |

Table 21-15. QEPCCTL Register Field Descriptions

| Bit | Field | Type | Reset | Description |
|-------|-----------|------|-------|--|
| 15-14 | FREE_SOFT | R/W | 0h | Emulation Control Bits QPOSCNT behavior: 0x0 = Position counter stops immediately on emulation suspend 0x1 = Position counter continues to count until the rollover 0x2 = Position counter is unaffected by emulation suspend 0x3 = Position counter is unaffected by emulation suspend QWDTMR behavior: 0x0 = Watchdog counter stops immediately 0x1 = Watchdog counter counts until WD period match roll over 0x2 = Watchdog counter is unaffected by emulation suspend 0x3 = Watchdog counter is unaffected by emulation suspend QUTMR behavior: 0x0 = Unit timer stops immediately 0x1 = Unit timer counts until period rollover 0x2 = Unit timer is unaffected by emulation suspend 0x3 = Unit timer is unaffected by emulation suspend QCTMR behavior: 0x0 = Capture Timer stops immediately 0x1 = Capture Timer counts until next unit period event 0x2 = Capture Timer is unaffected by emulation suspend 0x3 = Capture Timer is unaffected by emulation suspend |
| 13-12 | PCRM | R/W | 0h | Position counter reset mode 0h = Position counter reset on an index event 1h = Position counter reset on the maximum position 2h = Position counter reset on the first index event 3h = Position counter reset on a unit time event |
| 11-10 | SEI | R/W | 0h | Strobe event initialization of position counter 0h = Does nothing (action disabled) 1h = Does nothing (action disabled) 2h = Initializes the position counter on rising edge of the QEPS signal 3h = Clockwise Direction: Initializes the position counter on the rising edge of QEPS strobe. Counter Clockwise Direction: Initializes the position counter on the falling edge of QEPS strobe. |
| 9-8 | IEI | R/W | 0h | Index event initialization of position counter 0h = Do nothing (action disabled) 1h = Do nothing (action disabled) 2h = Initializes the position counter on the rising edge of the QEPI signal (QPOSCNT = QPOSINIT) 3h = Initializes the position counter on the falling edge of QEPI signal (QPOSCNT = QPOSINIT) |
| 7 | SWI | R/W | 0h | Software initialization of position counter 0h = Do nothing (action disabled) 1h = Initialize position counter (QPOSCNT = QPOSINIT). This bit is not cleared automatically |

Table 21-15. QEPCTL Register Field Descriptions (continued)

| Bit | Field | Type | Reset | Description |
|-----|-------|------|-------|--|
| 6 | SEL | R/W | 0h | Strobe event latch of position counter 0h = The position counter is latched on the rising edge of QEPS strobe (QPOSSLAT = POSCNT). Latching on the falling edge can be done by inverting the strobe input using the QSP bit in the QDECCTL register. 1h = Clockwise Direction: Position counter is latched on rising edge of QEPS strobe. Counter Clockwise Direction: Position counter is latched on falling edge of QEPS strobe. |
| 5-4 | IEL | R/W | 0h | Index event latch of position counter (software index marker) 0h = Reserved 1h = Latches position counter on rising edge of the index signal 2h = Latches position counter on falling edge of the index signal 3h = Software index marker. Latches the position counter and quadrature direction flag on index event marker. The position counter is latched to the QPOSILAT register and the direction flag is latched in the QEPSTS[QDLF] bit. This mode is useful for software index marking. |
| 3 | QPEN | R/W | 0h | Quadrature position counter enable/software reset 0h = Reset the eQEP peripheral internal operating flags/read-only registers. Control/configuration registers are not disturbed by a software reset. 1h = eQEP position counter is enabled |
| 2 | QCLM | R/W | 0h | eQEP capture latch mode 0h = Latch on position counter read by CPU. Capture timer and capture period values are latched into QCTMRLAT and QCPRDLAT registers when CPU reads the QPOSCNT register. 1h = Latch on unit time out. Position counter, capture timer and capture period values are latched into QPOSLAT, QCTMRLAT, and QCPRDLAT registers on unit time out. |
| 1 | UTE | R/W | 0h | eQEP unit timer enable 0h = Disable eQEP unit timer 1h = Enable unit timer |
| 0 | WDE | R/W | 0h | eQEP watchdog enable 0h = Disable the eQEP watchdog timer 1h = Enable the eQEP watchdog timer |

22.1 Overview

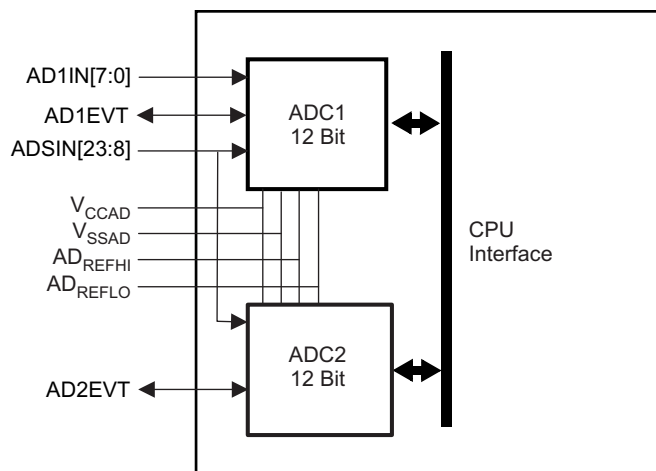

This microcontroller implements up to two instances of the ADC module. The main features of the ADC module are:

- Selectable 10-bit or 12-bit resolution, 10-bit mode is the default
- Successive-approximation-register (SAR) architecture
- Three conversion groups – Group1, Group2 and Event Group
- All three conversion groups can be configured to be hardware-triggered; group1 and group2 can also be triggered by software
- Conversion results are stored in a 64-word memory (SRAM)
 - These 64 words are divided between the three conversion groups and are configurable by software
 - Accesses to the conversion result RAM are protected by parity
- Flexible options for generating DMA requests for transferring conversion results
- Selectable channel conversion order:
 - Sequential conversions in ascending order of channel number, OR
 - User-defined channel conversion order with the Enhanced Channel Selection Mode
- Single or continuous conversion modes
- Embedded self-test logic for input channel failure detection (open / short to power / short to ground)
- Embedded calibration logic for offset error correction
- Enhanced Power-down mode
- External event pin (ADEVT) to trigger conversions
 - ADEVT is also programmable as general-purpose I/O
- Eight hardware events to trigger conversions

The two instances of the 12-bit ADC modules on the microcontroller share 16 analog input channels. The connections are shown in [Figure 22-1](#).

- ADC1 supports 24 channels.
- ADC2 supports 16 channels, all of which are shared with ADC1.
- When using both ADC1 and ADC2 on a shared channel, the sample windows must be identical such that the sample windows completely match each other or non-overlapping with a minimum of 2 ADC cycles buffer between the end of one ADC's sample window and the start of the other ADC's sample window.
- The reference voltages, as well as operating supply and ground, are shared between the two ADC cores.

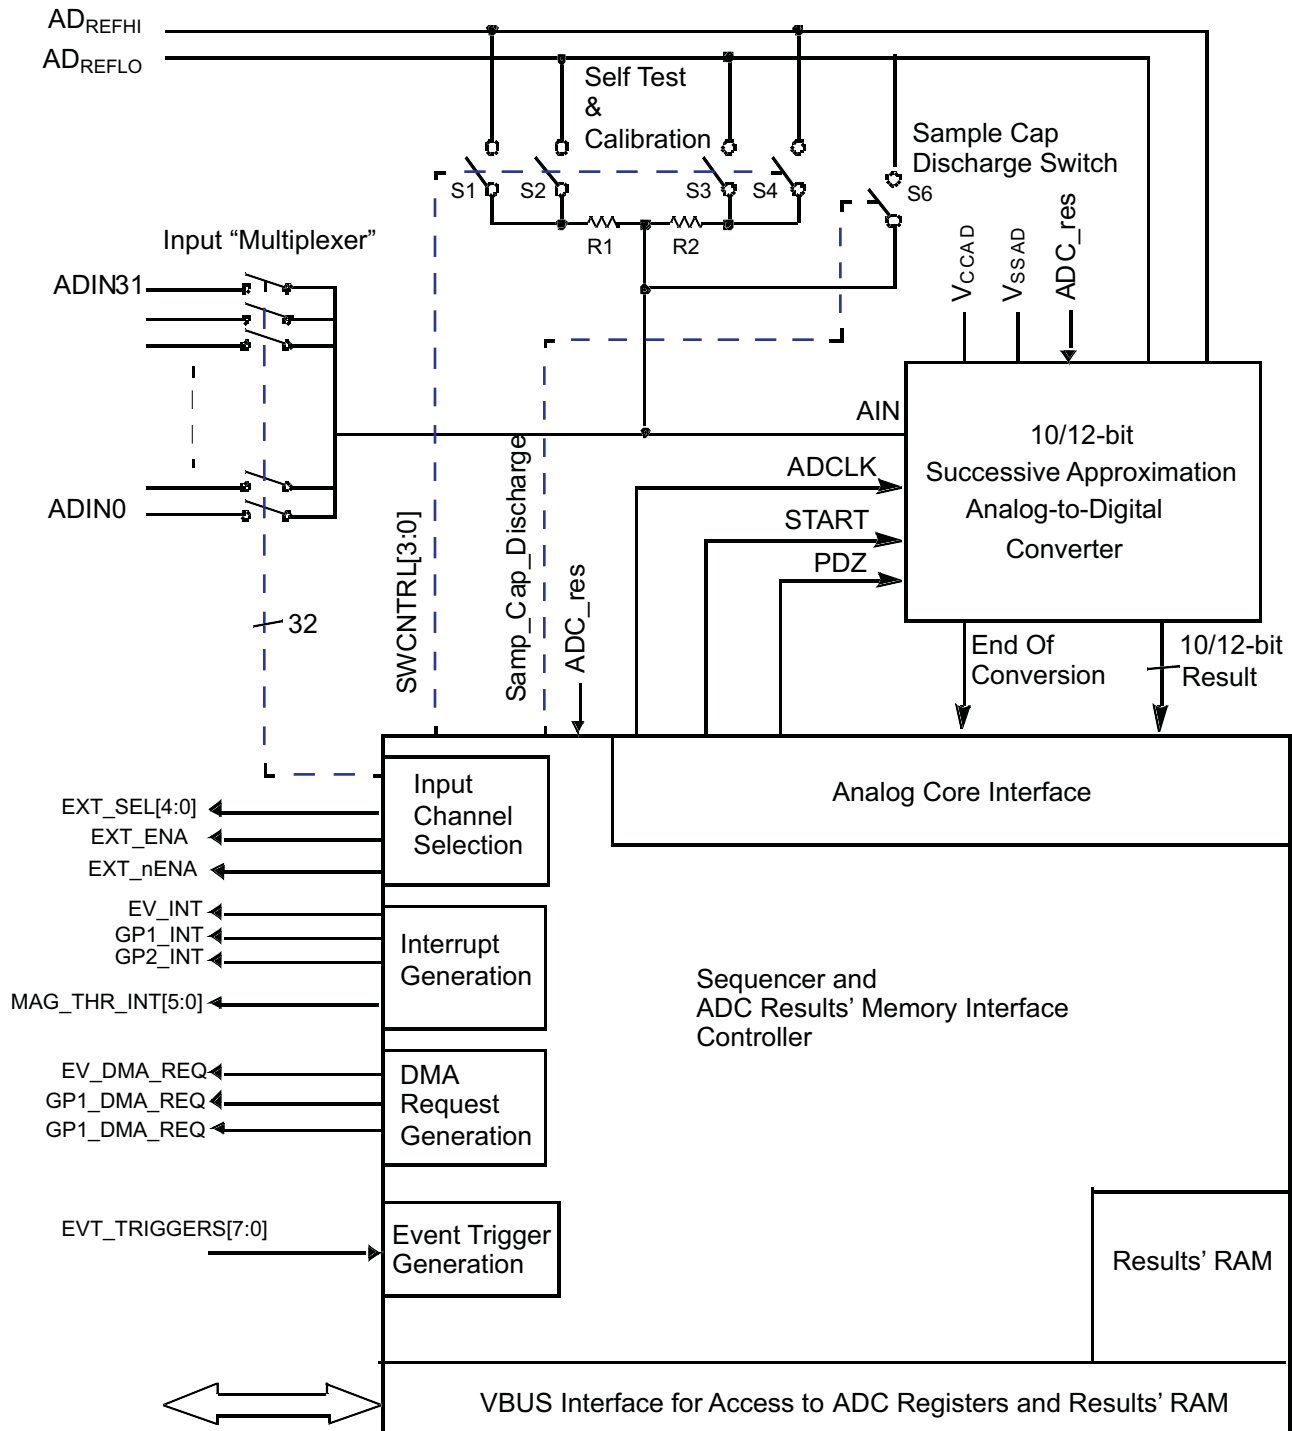

Figure 22-1. Channel Assignments of Two ADC Cores

22.2 Introduction

This section presents a brief functional description of the analog-to-digital converter (ADC) module. [Figure 22-2](#) illustrates the components of the ADC module.

Figure 22-2. ADC Block Diagram

22.2.1 Input Multiplexor

The input multiplexor (MUX) connects the selected input channel to the AIN input of the ADC core. The ADC1 module supports up to 24 inputs as shown in [Figure 22-2](#). The ADC2 module supports up to 16 inputs. The sequencer selects the channel to be converted. Enabling the enhanced channel selection mode also allows one or more of the analog input channels to be connected to the output of an external analog switch or multiplexor.

22.2.2 Self-Test and Calibration Cell

The ADC includes specific hardware that allows a software algorithm to detect open/short on an ADC analog input. It also allows the application program to calibrate the ADC. Also see [Section 22.8.1](#) and [Section 22.8.2](#).

22.2.3 Analog-to-Digital Converter Core

The ADC core is a combination voltage scaling, charge redistribution Successive Approximation Register (SAR) based analog-to-digital converter. The core can be configured for operation in 10-bit resolution (default) or 12-bit resolution. This is controlled by the sequencer logic. This selection applies to all conversions performed by the ADC module. It is not possible to convert some channels with a 12-bit resolution and some with a 10-bit resolution.

A single conversion from an analog input to a digital conversion result occurs in two distinct periods:

- Sampling Period:
 - The sequencer generates a START signal to the ADC core to signal the start of the sampling period.
 - The analog input signal is sampled directly on to the switched capacitor array during this period, providing an inherent sample-and-hold function.
 - The sampling period ends one full ADCLK after the falling edge of the START signal.
 - The sequencer can control the sampling period duration by configuring the conversion group's sample time control register (ADEVSAMP, ADG1SAMP, ADG2SAMP). This register controls the time for which the START signal stays high.
- Conversion Period:
 - The conversion period starts one full ADCLK after the falling edge of START.
 - One bit of the conversion result is output on each rising edge of ADCLK in the conversion period, starting with the most-significant bit first.
 - The conversion period is 12 ADCLK cycles in case of a 12-bit ADC, and is 10 ADCLK cycles in case of a 10-bit ADC.
 - The ADC core generates an End-Of-Conversion (EOC) signal to the sequencer at the end of the conversion period. At this time the complete 12-, or 10-bit conversion result is available.
 - The sequencer captures the ADC core conversion result output as soon as EOC is driven High.

The analog conversion range is determined by the reference voltages: AD_{REFHI} and AD_{REFLO} . AD_{REFHI} is the top reference voltage and is the maximum analog voltage that can be converted. An analog input voltage equal to AD_{REFHI} results in an output code of 0x3FF for 10-bit resolution and 0xFFF for 12-bit resolution. AD_{REFLO} is the bottom reference voltage and is the minimum analog voltage that can be converted. Applying an input equal to AD_{REFLO} results in an output code of 0x000. Both AD_{REFHI} and AD_{REFLO} must be chosen not to exceed the analog power supplies: V_{CCAD} and V_{SSAD} respectively. Input voltages between AD_{REFHI} and AD_{REFLO} produce a conversion result given by ([Equation 32](#)) for 10-bit resolution and ([Equation 33](#)) for 12-bit resolution.

$$DigitalResult = \frac{1024 \times (InputVoltage - AD_{REFLO})}{AD_{REFHI} - AD_{REFLO}} - 0.5 \quad (32)$$

$$DigitalResult = \frac{4096 \times (InputVoltage - AD_{REFLO})}{(AD_{REFHI} - AD_{REFLO})} - 0.5 \quad (33)$$

22.2.4 Sequencer

The sequencer coordinates the operations of the ADC, including the input multiplexor, the ADC core, and the result memory. In addition, the logic of the sequencer sets the status register flags when the conversion is ongoing, stopped, or finished.

All the features of the sequencer are discussed in detail in the following sections of this document.

22.2.5 Conversion Groups

Several applications require groups of channels to be converted using a single trigger source for example. There could also be some groups of channels identified which require a specific setting of the acquisition time. The ADC module supports three conversion groups for this purpose – Group1, Group2 and the Event Group.

Any of the available analog input channels can be assigned to any of the conversion groups. This also allows a particular channel to be repeatedly sampled by selecting it in multiple groups. There is an inherent priority scheme used when multiple conversion groups are triggered at once. The Event Group is the highest-priority, followed by the Group1 and then the Group2.

The Event Group is always hardware event-triggered. Group1 and Group2 are software-triggered by default and can be configured to be hardware-, or event-triggered as well. The triggering of conversions in each group is discussed in [Section 22.3.6](#).

Each conversion group has a separate set of control registers to:

- Select the input channels to be converted
- Configure the mode of conversion: single conversion sequence or continuous conversions
- Configure the input channel sampling time
- Configure the interrupt and/or DMA request generation conditions

22.3 Basic Features and Usage of the ADC

This section describes the usage of the basic features of the ADC module.

22.3.1 How to Select Between 12-bit and 10-bit Resolutions

The 10_12_BIT field of the ADC Operating Mode Control Register (ADOPMODECR) configures the ADC to be in 10-bit or 12-bit resolution mode.

- If 10_12_BIT = 0, the module is in 10-bit resolution mode. This is the default mode of operation.
- If 10_12_BIT = 1, the module is in 12-bit resolution mode.

22.3.2 How to Set Up the ADCLK Speed

The ADC sequencer generates the clock for the ADC core, ADCLK. The ADC core uses the ADCLK signal for its timing. The ADCLK is generated by dividing down the input clock to the ADC module, which is the VBUSP interface clock, VCLK. A 5-bit field (PS) in the ADC Clock Control Register (ADCLOCKCR) is used to divide down the VCLK by 1 up to 32. The ADCLK valid frequency range is specified in the device datasheet.

$$f_{\text{ADCLK}} = f_{\text{VCLK}} / (\text{PS} + 1)$$

The maximum frequency for ADCLK is specified in the device datasheet.

22.3.3 How to Set Up the Input Channel Acquisition Time

The signal acquisition time for each group is separately configurable using the ADG1SAMP[11:0], ADG2SAMP[11:0], and ADEVSAMP[11:0] registers.

The acquisition time is specified in terms of ADCLK cycles and ranges from a minimum of 2 ADCLK cycles to a maximum of 4098 ADCLK cycles.

For example, Group1 acquisition time, $t_{\text{ACQG1}} = \text{G1SAMP}[11:0] + 2$, in ADCLK cycles.

The minimum acquisition time is specified in the device datasheet. This time also depends on the impedance of the circuit connected to the analog input channel being converted.

22.3.4 How to Select an Input Channel for Conversion

The ADC module needs to be enabled first before selecting an input channel for conversion. The ADC module can be enabled by setting the ADC EN bit in the ADC Operating Mode Control Register (ADOPMODECR). Multiple input channels can be selected for conversion in each group. Only one input channel is converted at a time. The channels to be converted are configured in one or more of the three conversion groups' channel selection registers. Channels to be converted in Group1 are configured in the Group1 Channel-Select Register (ADG1SEL), those to be converted in Group2 are configured in the Group2 Channel-Select Register (ADG2SEL), and those to be converted in the Event Group are configured in the Event Group Channel-Select Register (ADEVSEL).

The description in this section only refers to the case when the enhanced channel selection mode is not enabled. Input channel selection in the enhanced channel selection mode is defined in [Section 22.4](#).

22.3.5 How to Select Between Single Conversion Sequence or Continuous Conversions

Each group has its own mode control register. The MODE field of these control registers allow the application to select between a single conversion sequence or continuous conversion mode.

NOTE: Selecting continuous conversion mode for all three groups

All three conversion groups cannot be configured to be in a continuous conversion mode. If the application configures the group mode control registers to enable continuous conversion mode for all three groups, then the Group2 will be automatically be configured to be in a single conversion sequence mode.

With conversions ongoing in continuous conversion mode, if the MODE field of a group is cleared, then that group switches to the single conversion sequence mode. Conversions for this group will stop once all channels selected for that group have been converted.

22.3.6 How to Start a Conversion

The conversion groups Group1 and Group2 are software-triggered by default. A conversion in these groups can be started just by writing the desired channels to the respective Channel-Select Registers. For example, in order to convert channels 0, 1, 2, and 3 in Group1 and channels 8, 9, 10, and 11 in Group2, the application just has to write 0x0000000F to ADG1SEL and 0x00000F00 to ADG2SEL. The ADC module will start by servicing the group that was triggered first, Group1 in this example.

The conversions for all groups are performed in ascending order of the channel number. For the Group1 the conversions will be performed in the order: channel 0 first, followed by channel 1, then channel 2, and then channel 3. The Group2 conversions will be performed in the order: channels 8, 9, 10, and 11.

The Event Group is only hardware-triggered. There are up to eight hardware event trigger sources defined for the ADC module. Check the device datasheet for a complete listing of these eight hardware trigger options.

The trigger source to be used needs to be configured in the ADEVSR register. Similar registers also exist for the Group1 and Group2 as these can also be configured to be event-triggered.

The polarity of the event trigger is also configurable, with a falling edge being the default.

An Event Group conversion starts when at least one channel is selected for conversion in this group, and when the defined event trigger occurs.

If any conversion group is configured to be in a continuous conversion mode, then it needs to only be triggered once. All the channels selected for conversion in that group will be converted repeatedly.

22.3.7 How to Know When the Group Conversion is Completed

Each conversion group has a status flag to indicate when its conversion has ended. See ADEVSR, ADG1SR, and ADG2SR. This bit is set when a conversion sequence for a group ends. This bit does is always set if a group is configured for continuous conversions.

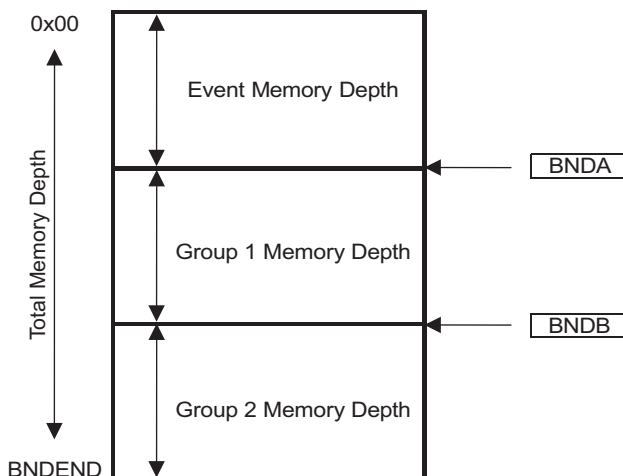

22.3.8 How Results are Stored in the Results' Memory

The ADC stores the conversion results in three separate memory regions in the ADC Results' RAM, one region for each group. Each memory region is a stack of buffers, with each buffer capable of holding one conversion result. The number of buffers allocated for each group is programmed by configuring the ADC module registers ADBNDCR and ADBNDEND.

ADBNDCR contains two 9-bit pointers BNDA and BNDB. BNDA, BNDB, and BNDEND are used to partition the total memory available into three memory regions as shown in Figure 22-3. Both BNDA and BNDB are pointers referenced from the start of the results' memory. BNDA specifies the number of buffers allocated for the Event Group conversion results in units of two buffers; BNDB specifies the number of buffers allocated for the Event Group plus Group1 in units of two buffers. Refer to for more details on configuring the ADC results' memory.

ADBNDEND contains a 3-bit field called BNDEND that configures the total memory available. The ADC module can support up to 1024 buffers. The device supports a maximum of 64 buffers for both the ADC modules.

Figure 22-3. FIFO Implementation

- Number of buffers for Event Group = $2 \times \text{BNDA}$
- Number of buffers for Group1 = $2 \times (\text{BNDB} - \text{BNDA})$
- Number of buffers for Group2 = Total number of buffers – $2 \times \text{BNDB}$

22.3.9 How to Read the Results from the Results' Memory

The CPU can read the conversion results in one of two ways:

1. By using the conversion results memory as a FIFO queue
2. By accessing the conversion results memory directly

22.3.9.1 Reading Conversion Results from a FIFO

The conversion results for each group can be accessed via a range of addresses provided to facilitate the use of the ARM Cortex-R4 CPU's Load-Multiple (LDM) instruction. A single read performed using the LDR instruction can also be used to read out a single conversion result. The results are read out from the group's memory region as a FIFO queue by reading from any location inside this address range. The conversion result that got stored first gets read first. A result that is read from the memory in this method is removed from the memory. For example, a read from any address in the range ADEVBUFFER (offset 90h to AFh) pulls out one conversion result from the Event Group memory.

Figure 22-4. Format of Conversion Result Read from FIFO, 12-bit ADC

| Offset Address Register | | 31 15 | 30 14 | 29 13 | 28 12 | 27 11 | 26 10 | 25 9 | 24 8 | 23 7 | 22 6 | 21 5 | 20 4 | 19 3 | 18 2 | 17 1 | 16 0 |
|-------------------------------|----------|----------|----------|----------|----------|----------|----------|---------|---------|---------|---------|---------|---------|---------|---------|---------|---------|
| 0x90 to 0xAF ADEVBUFFER | EV_EMPTY | Reserved | | | | | | | | | | | EV_CHID | | | | |
| | Reserved | | | | | EV_DR | | | | | | | | | | | |
| 0xB0 to 0xCF ADG1BUFFER | G1_EMPTY | Reserved | | | | | | | | | | | G1_CHID | | | | |
| | Reserved | | | | | G1_DR | | | | | | | | | | | |
| 0xD0 to 0xEF ADG2BUFFER | G2_EMPTY | Reserved | | | | | | | | | | | G2_CHID | | | | |
| | Reserved | | | | | G2_DR | | | | | | | | | | | |

Figure 22-5. Format of Conversion Result Read from FIFO, 10-bit ADC

| Offset Address Register | | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|-------------------------------|----------|---------|----|----|----|----|----|-------|----|----|----|----|----|----|----|----|----|
| | | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| 0x90 to 0xAF ADEVBUFFER | Reserved | | | | | | | | | | | | | | | | |
| | EV_EMPTY | EV_CHID | | | | | | EV_DR | | | | | | | | | |
| 0xB0 to 0xCF ADG1BUFFER | Reserved | | | | | | | | | | | | | | | | |
| | G1_EMPTY | G1_CHID | | | | | | G1_DR | | | | | | | | | |
| 0xD0 to 0xEF ADG2BUFFER | Reserved | | | | | | | | | | | | | | | | |
| | G2_EMPTY | G2_CHID | | | | | | G2_DR | | | | | | | | | |

Option to read channel id along with conversion result:

The application has an option to read the channel id along with the conversion result. This is controlled by the CHID field of the group's mode control register. If the option to read the channel id is not selected, the channel id field of the conversion result reads as zeros.

Protection against reading from empty FIFO:

There is also a hardware mechanism to protect the application from reading past the number of new conversion results held in the FIFO. Once all available conversion results have been read out of the FIFO by the application, a subsequent read from the FIFO causes the mechanism to indicate that the FIFO is empty by setting the EMPTY field.

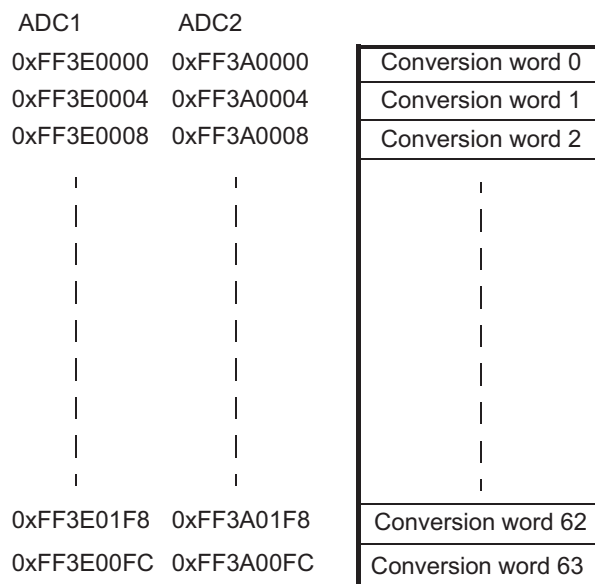

Debug / Emulation Support:

For debug purposes, each conversion group also provides an address that the application can read from for extracting the group's conversion results. However, no status flags for a conversion group are affected by reading from these emulation buffer addresses. For example, reading from ADEVEMUBUFFER (offset 0xF0) returns the next result in the Event Group buffer but does not actually remove that result from the buffer or change the amount of data held in the buffer.

22.3.9.2 Reading Conversion Results Directly from the Conversion Results' Memory

The conversion result memory is part of the device's memory map. The base address for the ADC1 result memory is 0xFF3E0000, while that for the ADC2 result memory is 0xFF3A0000.

Figure 22-6. ADC Memory Mapping

The application can identify the address ranges for each of the three memory regions for the three conversion groups after performing the segmentation as described in [Section 22.3.8](#). It is up to the application to read the desired results from the three conversion groups. The formats of the conversion results when reading from RAM directly are shown in [Figure 22-7](#) and [Figure 22-8](#).

Figure 22-7. Format of Conversion Result Directly Read from ADC RAM, 12-bit ADC

| | 31 15 | 30 14 | 29 13 | 28 12 | 27 11 | 26 10 | 25 9 | 24 8 | 23 7 | 22 6 | 21 5 | 20 4 | 19 3 | 18 2 | 17 1 | 16 0 |

| | channel id [3-0] | | | | | 12-bit conversion result | | | | | | | | | | |

Figure 22-8. Format of Conversion Result Directly Read from ADC RAM, 10-bit ADC

| | | | | | | | | | | | | | | | | | |
|-----------------|----------|------------------|----|----|----|----|--------------------------|----|----|----|----|----|----|----|----|----|--|
| | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | |
| | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 | |
| ADC RAM address | Reserved | | | | | | | | | | | | | | | | |
| | Rsvd | channel id [4-0] | | | | | 10-bit conversion result | | | | | | | | | | |

Note that there is no EMPTY field to protect the application from reading data that has been previously read.

Each group does have a separate register which holds the address in the group's result memory where the ADC will write the next conversion result. These are the ADEV RAMWRADDR, ADG1RAMWRADDR, and ADG2RAMWRADDR registers. The application can use this information to calculate how many valid conversion results are available to be read.

Benefit of reading conversion results directly from ADC RAM:

The application does not have to read out conversion results sequentially as in the case of reading from a FIFO. As a result, the application can selectively read the conversion results for any particular input channel of interest without having to read other channels' conversion results.

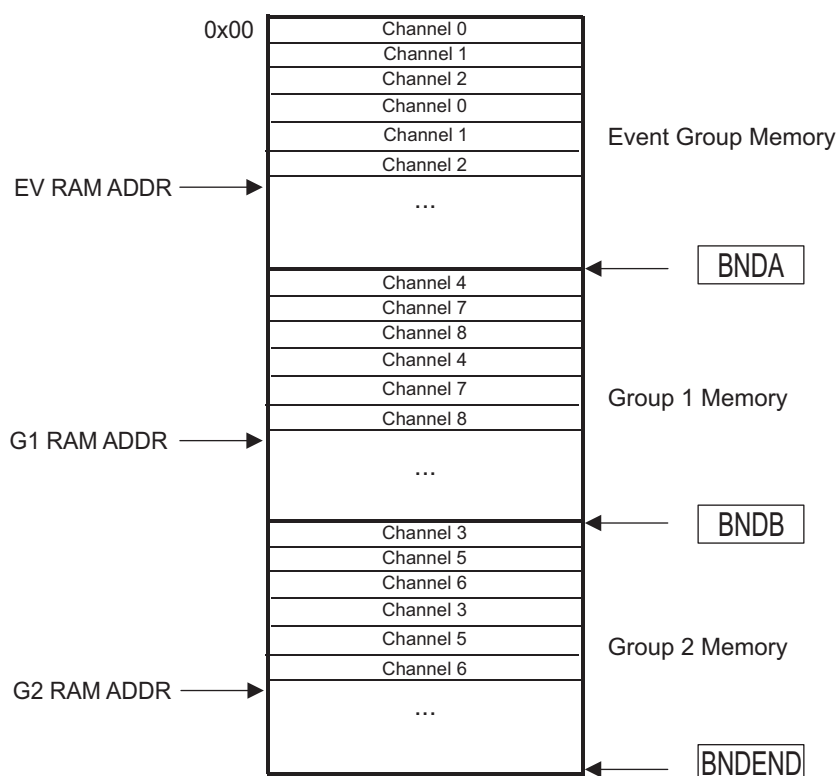

22.3.9.3 Example

Suppose that channels 0, 1, and 2 are selected for conversion in the Event Group, channels 4, 7, and 8 are selected for conversion in group 1, and channels 3, 5, and 6 are selected for conversion in group 2. The conversion results will get stored in the three memory regions as shown in Figure 22-9.

Suppose that the CPU wants to read out the results for the Event Group from a FIFO queue. The CPU needs to read from any address in the range ADEVBUFFER (offset 0x90 to 0xAF) multiple times, or do a "load multiple" from this range of addresses. This will cause the ADC to return the results for channel 0, then channel 1, then channel 2, then channel 0, and so on for each read access to this address range.

Now suppose that the application wants to read out the results for the group 1 from the RAM directly. The conversion results for the group 1 are accessible starting from address ADC RAM Base Address + BNDA. Also, it is known that the first result at this address is for the input channel 4, the next one is for input channel 7, and so on. So the application can selectively read the conversion results for only one channel if so desired.

Figure 22-9. Conversion Results Storage

22.3.10 How to Stop a Conversion

A group's conversion can be stopped by clearing the group's channel select register.

22.3.11 Example Sequence for Basic Configuration of ADC Module

The following sequence is necessary to configure the ADC to convert channels 0, 2, 4, and 8 in single-conversion mode using Group1:

1. Write 0 to the Reset Control Register (ADRSTCR) to release the module from the reset state
2. Write 1 to the ADC_EN bit of the Operating Mode Control Register (ADOPMODECR) to enable the ADC state machine
3. Configure the ADCLK frequency by programming the desired divider into the Clock Control Register (ADCLOCKCR)
4. Configure the acquisition time for the group that is to be used. For example, configure the Group1 Sampling Time Control Register (ADG1SAMP) to set the acquisition time for Group1.
5. Select the channels that need to be converted in Group1 by writing to the Group1 Channel Select Register (ADG1SEL). In this example, a value of 0x115 needs to be written to ADG1SEL in order to select channels 0, 2, 4, and 8 for conversion in Group1.
 - The ADC sequencer will start the Group1 conversions as soon as the write to the ADG1SEL register is completed.
6. Wait for the G1_END bit to be set in the Group1 Conversion Status Register (ADG1SR). This bit gets set when all the channels selected for conversion in Group1 are converted and the results are stored in the Group1 memory.
7. Read the conversion results by reading from the Group1 FIFO access location (ADG1BUFFER) or by reading directly from the Group1 results' memory.

22.4 Advanced Conversion Group Configuration Options

Figure 22-10 shows the operating mode control registers and the status registers for each of the three conversion groups. The register addresses shown are offsets from the base address. The ADC1 register frame base address is FFF7 C000h and the ADC2 register frame base address is FFF7 C200h.

Figure 22-10. ADC Groups' Operating Mode Control and Status Registers

| Offset Address Register | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

22.4.1 Group Trigger Options

The Group1 and Group2 operating mode control registers have an extra control bit: HW_TRIG. This bit configures the group to be hardware event-triggered instead of software-triggered, which is the default.

When a group is configured to be event-triggered, the group conversion starts when at least one channel is selected for conversion in this group, and when the defined event trigger occurs. The event trigger source is defined for each group in the ADEVSRC, ADG1SRC, and the ADG2SRC registers. The actual connections used as the event trigger sources are defined in the device datasheet for both the ADC modules.

22.4.2 Analog Input Channel Selection Mode Options

The ADC modules on this device support two different modes for selecting the analog input channel to be converted. These are the sequential channel selection mode (default), and the enhanced channel selection mode. These two modes are now described:

22.4.2.1 Sequential Channel Selection Mode

This is the default mode and allows the ADC module to be used in a backwards compatible mode to the ADC module on other Hercules ARM Safety MCUs from Texas Instruments. As discussed in [Section 22.3.4](#), an analog input channel can be selected for conversion in one or more conversion groups by setting the bit corresponding to that channel number in the group's channel select register.

22.4.2.2 Enhanced Channel Selection Mode

There are some important concepts related to the enhanced channel selection mode. These are defined first:

- Look-Up Table

This is a 32-word deep memory-mapped region used to define the analog input channel number to be converted. The LUTs for the three groups are stacked together so that the entire LUT occupies 96 words. Each word is aligned on a 32-bit boundary. The LUTs for ADC1 start at 0xFF3E2000 and the LUTs for ADC2 start at 0xFF3A2000.

- Conversion Group Sub-Sequence

A group sub-sequence is defined as the conversion for a set of channels that is converted on each conversion trigger. The number of channels selected for conversion in a group sub-sequence is defined by the number of bits that are set in the group's channel select register. For example, setting bits 0, 1, 29, and 31 in ADG1SEL means that each Group1 conversion sub-sequence consists of 4 conversions.

- LUT Index

A "CURRENT_COUNT" register for each group is maintained as an index into that group's LUT. This register increments each time a channel conversion is completed. Therefore, as its name suggests, a read from this register returns the number of conversions completed since the last write to the group's channel select register. The CURRENT_COUNT register resets to all zeros under any of the following conditions:

1. The ADC peripheral is reset via a global peripheral reset
2. The ADC peripheral is reset via the ADC Reset Control Register,
3. The CURRENT_COUNT becomes equal to the MAX_COUNT defined for that conversion group
4. The application writes zeros to the CURRENT_COUNT register
5. The conversion group's result RAM is reset

- Maximum Number of Conversions

A "MAX_COUNT" register for each conversion group stores the maximum number of conversions to be performed before the index into a group's LUT is reset to zero. This register can be programmed to a value between 0 and 31. It is recommended to program the MAX_COUNT register with a value that is one less than a multiple of the number of channels in that group's conversion sub-sequence (number of bits that are set in the group's channel select register).

22.4.2.2.1 Look-Up Table Details

As described earlier, each conversion group has a look-up table (LUT) that is used when the enhanced channel selection mode is enabled. This look-up table starts at an offset of 8kB from the base of the ADC results RAM. The LUT holds 32 entries for each of the three conversion groups. The first 32 entries are for the event group, the next 32 entries are for Group1 and the last 32 entries are for Group2. [Figure 22-11](#) shows an example LUT entry for the Event group.

Figure 22-11. Example Look-Up Table Entry

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 22-1. ADC Look-Up Table Field Descriptions

| Bit | Field | Value | Description |
|-------|--------------------|-------|---|
| 31–13 | Reserved | 0 | Reads return zeros, writes have no effect. |
| 12–8 | EV_EXT_CHN_MUX_SEL | | This field defines the external analog mux select that is output from the ADC module when the Event group CURRENT_COUNT register points to this LUT entry, and when the Event group conversion is triggered with the enhanced channel selection mode enabled. |
| 7–5 | Reserved | 0 | Reads return zeros, writes have no effect. |
| 4–0 | EV_INT_CHN_MUX_SEL | | <p>This field defines the internal analog mux select that is output from the ADC module when the Event group CURRENT_COUNT register points to this LUT entry, and when the Event group conversion is triggered with the enhanced channel selection mode enabled.</p> <p>This can be a value between 0 and 31, which corresponds to the internal analog input channel number between 0 and 31. Note that this device only supports 24 input channels for ADC1 and 16 input channels for ADC2. If the application configures an unavailable channel number in the EV_INT_CHN_MUX_SEL field, the ADC will still perform the conversion and the result will be indeterminate.</p> |

Consider the example conversion Group1 configuration shown in [Figure 22-12](#). Only bits 0 and 31 of ADG1SEL are set. Assume that all other bits in this register are zeros.

In case of the default sequential channel selection mode, the write to the ADG1SEL register would cause the Group1 conversions to start with channel 0 followed by channel 31. The conversions would then stop or repeat in this order depending on whether Group1 is in single or continuous conversion mode.
