

## WIDE-INPUT SYNCHRONOUS BUCK CONTROLLER

Check for Samples: [TPS40060](#), [TPS40061](#)

### FEATURES

- Operating Input Voltage 10 V to 55 V
- Input Voltage Feed-Forward Compensation
- < 1% Internal 0.7-V Reference
- Programmable Fixed-Frequency, Up to 1-MHz Voltage Mode Controller
- Internal Gate Drive Outputs for High-Side P-Channel and Synchronous N-Channel MOSFETs
- 16-Pin PowerPAD™ Package ( $\theta_{JC} = 2^{\circ}\text{C/W}$ )
- Thermal Shutdown
- Externally Synchronizable
- Programmable High-Side Sense Short Circuit Protection
- Programmable Closed-Loop Soft-Start
- TPS40060 Source Only/TPS40061 Source/Sink

### APPLICATIONS

- Networking Equipment
- Telecom Equipment
- Base Stations
- Servers

### DESCRIPTION

The TPS40060 and TPS40061 are high-voltage, wide input (10 V to 55 V) synchronous, step-down converters.

This family of devices offers design flexibility with a variety of user programmable functions, including; soft-start, UVLO, operating frequency, voltage feed-forward, high-side current limit, and loop compensation. These devices are also synchronizable to an external supply.

The TPS40060 and TPS40061 incorporate MOSFET gate drivers for external P-channel high-side and N-channel synchronous rectifier (SR) MOSFETs. Gate drive logic incorporates anti-cross conduction circuitry to prevent simultaneous high-side and synchronous rectifier conduction.

### SIMPLIFIED APPLICATION DIAGRAM

UDG-02157

Please be aware that an important notice concerning availability, standard warranty, and use in critical applications of Texas Instruments semiconductor products and disclaimers thereto appears at the end of this data sheet.

PowerPAD is a trademark of Texas Instruments.

This integrated circuit can be damaged by ESD. Texas Instruments recommends that all integrated circuits be handled with appropriate precautions. Failure to observe proper handling and installation procedures can cause damage.

ESD damage can range from subtle performance degradation to complete device failure. Precision integrated circuits may be more susceptible to damage because very small parametric changes could cause the device not to meet its published specifications.

### ORDERING INFORMATION

T <sub>A</sub>	LOAD CURRENT	PACKAGE <sup>(1)</sup>	PART NUMBER
-40°C to 85°C	SOURCE <sup>(2)</sup>	Plastic HTSSOP (PWP)	TPS40060PWP
	SOURCE/SIN <sup>(2)</sup>	Plastic HTSSOP (PWP)	TPS40061PWP

- (1) The PWP package is also available taped and reeled. Add an R suffix to the device type (i.e., TPS40060PWPR). See the [Application Information](#) of the data sheet for PowerPAD drawing and layout information.
- (2) See [Application Information](#) section.

### ABSOLUTE MAXIMUM RATINGS

over operating free-air temperature range unless otherwise noted<sup>(1)</sup>

			TPS40060 TPS40061
V <sub>IN</sub>	Input voltage range	VIN	60 V
		VFB, SS/SD, SYNC	-0.3 V to 6 V
		SW	-0.3 V to 60 V or VIN+5 V (whichever is less)
		SW. transient < 50 ns	-2.5 V
V <sub>OUT</sub>	Output voltage range	COMP, RT, KFF, SS	-0.3 V to 6 V
I <sub>IN</sub>	Input current	KFF	5 mA
I <sub>OUT</sub>	Output current	RT	200 μA
T <sub>J</sub>	Operating junction temperature range		-40°C to 125°C
T <sub>stg</sub>	Storage temperature		-55°C to 150°C
Lead temperature 1,6 mm (1/16 inch) from case for 10 seconds			260°C

- (1) Stresses beyond those listed under *absolute maximum ratings* may cause permanent damage to the device. These are stress ratings only, and functional operation of the device at these or any other conditions beyond those indicated under *recommended operating conditions* is not implied. Exposure to absolute-maximum-rated conditions for extended periods may affect device reliability.

### RECOMMENDED OPERATING CONDITIONS

		MIN	NOM	MAX	UNIT
V <sub>IN</sub>	Input voltage	10		55	V
T <sub>A</sub>	Operating free-air temperature	-40		85	°C

PWP PACKAGE <sup>(1)(2)</sup>  
(TOP VIEW)

- (1) For more information on the PWP package, refer to TI Technical Brief ([SLMA002](#)).
- (2) PowerPAD™ heat slug must be connected to SGND (Pin 5), or electrically isolated from all other pins.

## ELECTRICAL CHARACTERISTICS

$T_A = -40^{\circ}\text{C}$  to  $85^{\circ}\text{C}$ ,  $V_{IN} = 24 V_{dc}$ ,  $R_T = 165 k\Omega$ ,  $I_{KFF} = 113 \mu\text{A}$ ,  $f_{SW} = 300 \text{ kHz}$ , all parameters at zero power dissipation (unless otherwise noted)

PARAMETER	TEST CONDITIONS	MIN	TYP	MAX	UNIT
<b>INPUT SUPPLY</b>					
$V_{IN}$ Input voltage range, $V_{IN}$		10		55	V
<b>OPERATING CURRENT</b>

### Terminal Functions

TERMINAL NAME	NO.	I/O	DESCRIPTION
BP5	3	O	5-V reference. This pin should be bypassed to ground with a 0.1- $\mu$ F ceramic capacitor. This pin may be used with an external DC load of 1 mA or less.
BP10	11	O	10-V reference used for gate drive of the N-channel synchronous rectifier. This pin should be bypassed by a 1- $\mu$ F ceramic capacitor. This pin may be used with an external DC load of 1 mA or less.
BPN10	13	O	Negative 8-V reference with respect to VIN. This voltage is used to provide gate drive for the high side P-channel MOSFET. This pin should be bypassed to VIN with a 0.1- $\mu$ F capacitor
COMP	8	I	Output of the error amplifier, input to the PWM comparator. A feedback network is connected from this pin to the VFB pin to compensate the overall loop. The comp pin is internally clamped above the peak of the ramp to improve large signal transient response.
HDRV	14	O	Floating gate drive for the high-side P-channel MOSFET. This pin switches from VIN (MOSFET off) to BPN10 (MOSFET on).
ILIM	16	I	Current limit pin, used to set the overcurrent threshold. An internal current sink from this pin to ground sets a voltage drop across an external resistor connected from this pin to VIN. The voltage on this pin is compared to the voltage drop (VIN -SW) across the high side MOSFET during conduction.
KFF	1	I	A resistor is connected from this pin to VIN to program the amount of voltage feed-forward. The current fed into this pin is internally divided and used to control the slope of the PWM ramp.
LDRV	10	I	Gate drive for the N-channel synchronous rectifier. This pin switches from BP10 (MOSFET on) to ground (MOSFET off).
PGND	9		Power ground reference for the device. There should be a low-impedance connection from this point to the source of the power MOSFET.
RT	2	I	A resistor is connected from this pin to ground to set the internal oscillator ramp charging current and switching frequency.
SGND	5		Signal ground reference for the device.
SS/SD	6	I	Soft-start programming pin. A capacitor connected from this pin to ground programs the soft-start time. The capacitor is charged with an internal current source of 2.3 $\mu$ A. The resulting voltage ramp on the SS pin is used as a second non-inverting input to the error amplifier. The output voltage begins to rise when $V_{SS/SD}$ is approximately 0.85 V. The output continues to rise and reaches regulation when $V_{SS/SD}$ is approximately 1.55 V. The controller is considered shut down when $V_{SS/SD}$ is 125 mV or less. All internal circuitry is inactive. The internal circuitry is enabled when $V_{SS/SD}$ is 210 mV or greater. When $V_{SS/SD}$ is less than approximately 0.85 V, the outputs cease switching and the output voltage ( $V_{OUT}$ ) decays while the internal circuitry remains active.
SW	12	I	This pin is connected to the switched node of the converter and used for overcurrent sensing. This pin is used for zero current sensing in the TPS40060.
SYNC	4	I	Synchronization input for the device. This pin can be used to synchronize the oscillator to an external master frequency.
VFB	7	I	Inverting input to the error amplifier. In normal operation the voltage on this pin is equal to the internal reference voltage, 0.7 V.
VIN	15	I	Supply voltage for the device.

SIMPLIFIED BLOCK DIAGRAM

## APPLICATION INFORMATION

The TPS40060/61 family of parts allows the user to optimize the PWM controller to the specific application.

The TPS40061 is the controller of choice for synchronous buck designs which will include most applications. It has two quadrant operation and will source or sink output current. This provides the best transient response.

The TPS40060 operates in one quadrant and sources output current only, allowing for paralleling of converters and ensures that one converter does not sink current from another converter. This controller also emulates a standard buck converter at light loads where the inductor current goes discontinuous. At continuous output inductor currents the controller operates as a synchronous buck converter to optimize efficiency.

### SW NODE RESISTOR

The SW node of the converter will be negative during the *dead time* when both the upper and lower MOSFETs are off. The magnitude of this negative voltage is dependent on the lower MOSFET body diode and the output current which flows during this dead time. This negative voltage could affect the operation of the controller, especially at low input voltages.

Therefore, a 10-Ω resistor must be placed between the lower MOSFET drain and pin 12 (SW) of the controller as shown in [Figure 14](#) as  $R_{SW}$ .

### SETTING THE SWITCHING FREQUENCY (PROGRAMMING THE CLOCK OSCILLATOR)

The TPS40060 and TPS40061 have independent clock oscillator and ramp generator circuits. The clock oscillator serves as the master clock to the ramp generator circuit. The switching frequency,  $f_{SW}$  in kHz, of the clock oscillator is set by a single resistor ( $R_T$ ) to ground. The clock frequency is related to  $R_T$ , in kΩ by [Equation 1](#) and the relationship is charted in [Figure 2](#).

$$R_T = \left( \frac{1}{f_{SW} \times 17.82 \times 10^{-6}} - 23 \right) \text{ k}\Omega \quad (1)$$

### PROGRAMMING THE RAMP GENERATOR CIRCUIT

The ramp generator circuit provides the actual ramp used by the PWM comparator. The ramp generator provides voltage feed-forward control by varying the PWM ramp slope with line voltage, while maintaining a constant ramp magnitude. Varying the PWM ramp directly with line voltage provides excellent response to line variations since the PWM does not have to wait for loop delays before changing the duty cycle. (See [Figure 1](#)).

UDG-02131

Figure 1. Voltage Feed-Forward Effect on PWM Duty Cycle

The PWM ramp must be faster than the master clock frequency or the PWM is prevented from starting. The PWM ramp time is programmed via a single resistor ( $R_{KFF}$ ) pulled up to  $V_{IN}$ .  $R_{KFF}$  is related to  $R_T$ , and the minimum input voltage,  $V_{IN(min)}$  through the following:

$$R_{KFF} = (V_{IN(min)} - 3.5) \times (65.27 \times R_T + 1502) \quad (\Omega)$$

where:

- $V_{IN}$  is the desired start-up (UVLO) input voltage
  - $R_T$  is the timing resistor in  $k\Omega$
- (2)

See the section on [UVLO operation](#) for further description.

The curve showing the feedforward impedance required for a given switching frequency,  $f_{SW}$ , at various input voltages is shown in [Figure 3](#).

For low input voltage and high duty cycle applications, the voltage feed-forward may limit the duty cycle prematurely. This does not occur for most applications. The voltage control loop controls the duty cycle and regulates the output voltages. For more information on large duty cycle operation, refer to Application Note ([SLUA310](#)).

Figure 2.

Figure 3.

## UVLO OPERATION

The TPS40060 and TPS40061 use both fixed and variable (user programmable) UVLO protection. The fixed UVLO monitors the BP10 and BP5 bypass voltages. The UVLO circuit holds the soft-start low until the BP5 and BP10 voltage rails have exceeded their thresholds and the input voltage has exceeded the user programmable undervoltage threshold.

The TPS40060 and TPS40061 use the feed-forward pin, KFF, as a user programmable low-line UVLO detection. This variable low-line UVLO threshold compares the PWM ramp duration to the oscillator clock period. An undervoltage condition exists if the device receives a clock pulse before the ramp has reached 90% of its full amplitude. The ramp duration is a function of the ramp slope, which is directly related to the current into the KFF pin. The KFF current is a function of the input voltage and the resistance from KFF to the input voltage. The KFF resistor can be referenced to the oscillator frequency as described in [Equation 3](#):

$$R_{KFF} = (V_{IN(min)} - 3.5) \times (65.27 \times R_T + 1502) \quad (\Omega)$$

where:

- $V_{IN}$  is the desired start-up (UVLO) input voltage
  - $R_T$  is the timing resistor in  $k\Omega$
- (3)

The variable UVLO function utilizes a 3-bit full adder to prevent spurious shut-downs or turn-ons due to spikes or fast line transients. When the adder reaches a total of seven counts in which the ramp duration is shorter than the clock cycle a powergood signal is asserted, a soft-start initiated, and the upper and lower MOSFETs are turned off.

Once the soft-start is initiated, the UVLO circuit must see a total count of seven cycles in which the ramp duration is longer than the clock cycle before an undervoltage condition is declared (See Figure 4).

UDG-02132

Figure 4. Undervoltage Lockout Operation

Figure 5.

The impedance of the input voltage can cause the input voltage, at the TPS4006x, to sag when the converter starts to operate and draw current from the input source. Therefore, there is voltage hysteresis that prevents nuisance shutdowns at the UVLO point.

With RT chosen to select the operating frequency and RKFF chosen to select the start-up voltage, the amount of hysteresis voltage is shown in [Figure 5](#).

## PROGRAMMING SOFT START

TPS4006x uses a closed-loop approach to ensure a controlled ramp on the output during start-up. Soft-start is programmed by charging an external capacitor ( $C_{SS}$ ) via an internally generated current source. The voltage on  $C_{SS}$  minus 0.85 V, is fed into a separate non-inverting input to the error amplifier (in addition to FB and 0.7-V  $V_{REF}$ ). The loop is closed on the lower of the ( $V_{CSS} - 0.85$  V) voltage or the internal reference voltage (0.7-V  $V_{REF}$ ). Once the ( $V_{CSS} - 0.85$  V) voltage rises above the internal reference voltage, regulation is based on the internal reference. To ensure a controlled ramp-up of the output voltage the soft-start time should be greater than the L- $C_O$  time constant as described in [Equation 4](#).

$$t_{START} \geq 2\pi \times \sqrt{L \times C_O} \quad (\text{seconds}) \quad (4)$$

There is a direct correlation between  $t_{START}$  and the input current required during start-up. The faster  $t_{START}$ , the higher the input current required during start-up. This relationship is describe in more detail in the section titled, [Programming the Current Limit](#), which follows. The soft-start capacitance,  $C_{SS}$ , is described in [Equation 5](#).

For applications in which the  $V_{IN}$  supply ramps up slowly, (typically between 50 ms and 100 ms) it may be necessary to increase the soft-start time to between approximately 2 ms and 5 ms to prevent nuisance UVLO tripping. The soft-start time should be longer than the time that the  $V_{IN}$  supply transitions between 6 V and 7 V.

$$C_{SS} = \frac{2.3 \mu A}{0.7 V} \times t_{START} \quad (\text{Farads}) \quad (5)$$

## PROGRAMMING CURRENT LIMIT

This device uses a two-tier approach for overcurrent protection. The first tier is a pulse-by-pulse protection scheme. Current limit is implemented on the high-side MOSFET by sensing the voltage drop across the MOSFET when the gate is driven low. The MOSFET voltage is compared to the voltage dropped across a resistor connected from VIN pin to the ILIM pin when driven by a constant current sink. If the voltage drop across the MOSFET exceeds the voltage drop across the ILIM resistor, the switching pulse is immediately terminated. The MOSFET remains off until the next switching cycle is initiated.

The second tier consists of a fault counter. The fault counter is incremented on an overcurrent pulse and decremented on a clock cycle without an overcurrent pulse. When the counter reaches seven (7) a restart is issued and seven soft-start cycles are initiated. Both the upper and lower MOSFETs are turned off during this period. The counter is decremented on each soft-start cycle. When the counter is decremented to zero, the PWM is re-enabled. If the fault has been removed the output starts up normally. If the output is still present the counter counts seven overcurrent pulses and re-enters the second-tier fault mode. See [Figure 7](#) for typical overcurrent protection waveforms.

The minimum current limit setpoint ( $I_{LIM}$ ) depends on  $t_{START}$ ,  $C_O$ ,  $V_O$ , and the load current at start-up ( $I_{LOAD}$ ).

$$I_{LIM} = \left[ \frac{(C_O \times V_O)}{t_{START}} \right] + I_{LOAD} \quad (\text{A}) \quad (6)$$

The current limit programming resistor ( $R_{ILIM}$ ) is calculated using [Equation 7](#). Care must be taken in choosing the values used for  $V_{OS}$  and  $I_{SINK}$  in the equation. In order to ensure the output current at the overcurrent level, the minimum value of  $I_{SINK}$  and the maximum value of  $V_{OS}$  must be used.

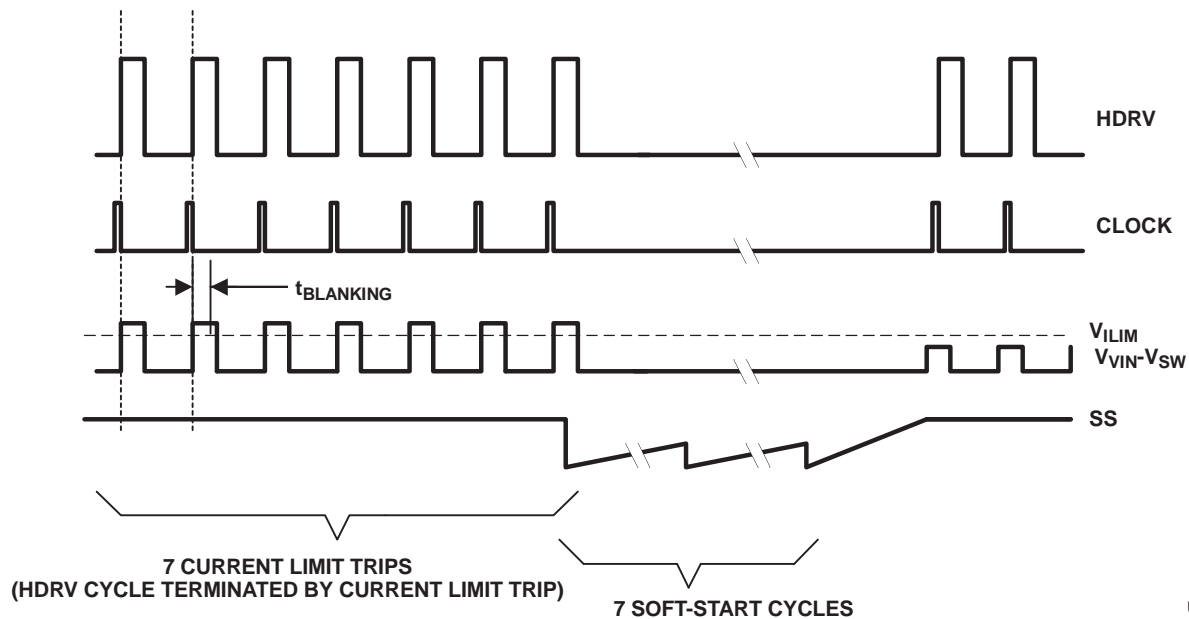

$$R_{ILIM} = \frac{I_{OC} \times R_{DS(on)[max]}}{I_{SINK}} + \frac{V_{OS}}{I_{SINK}} \quad (\Omega)$$

where:

- $I_{SINK}$  is the current into the ILIM pin and is nominally 8.3  $\mu\text{A}$ , minimum
  - $I_{OC}$  is the overcurrent setpoint which is the DC output current plus one-half of the peak inductor current
  - $V_{OS}$  is the overcurrent comparator offset and is 50 mV maximum
- (7)

## BP5, BP10 AND BPN10 INTERNAL VOLTAGE REGULATOR

Start-up characteristics of the BP5, BP10 and BPN10 regulators are shown in [Figure 7](#). Slight variations in the BP5 occurs dependent upon the switching frequency. Variation in the BPN10 and BP10 regulation characteristics is also based on the load presented by switching the external MOSFETs.

UDG-02136

Figure 6. Typical Current Limit Protection Waveforms

Figure 7.

### CALCULATING THE BPN10 AND BP10V BYPASS CAPACITOR

The BPN10 capacitance provides energy for the high-side driver. The BPN10 capacitor should be a good quality, high-frequency capacitor. The size of the bypass capacitor depends on the total gate charge of the high-side MOSFET and the amount of droop allowed on the bypass capacitor. The BPN10 capacitance is described in [Equation 8](#).

$$C_{\text{BPN10}} = \frac{Q_g}{\Delta V} \quad (\text{F}) \quad (8)$$

The 10-V reference pin, BP10V needs to provide energy for the synchronous MOSFET gate drive via the BP10V capacitor. Neglecting any efficiency penalty, the BP10V capacitance is described in [Equation 9](#).

$$C_{\text{BP10V}} = \frac{Q_{\text{gSR}}}{\Delta V} \quad (\text{F}) \quad (9)$$

## SYNCHRONIZING TO AN EXTERNAL SUPPLY

The TPS4006x can be synchronized to an external clock through the SYNC pin. The SW node rises on the falling edge of the SYNC signal. The synchronization frequency should be in the range of 20% to 30% higher than its programmed free-run frequency. The clock frequency at the SYNC pin replaces the master clock generated by the oscillator circuit. Pulling the SYNC pin low programs the TPS4006x to freely run at the frequency programmed by  $R_T$ .

Internally, the SYNC pin has a pull-down current between 5  $\mu\text{A}$  and 10  $\mu\text{A}$ . In order to synchronize the device to an external clock signal, the SYNC pin has to be overdriven from the external clock circuit. Normal logic gates or an external MOSFET with a pull-up resistor of 10 k $\Omega$  is adequate.

Internally there is a delay of between approximately 50 ns and 100 ns from the time the SYNC pin is pulled low and the HDRV signal goes low to turn on the upper MOSFET. Additionally, there is some delay as the MOSFET gate charges to turn on the upper MOSFET, typically between 20 ns and 50 ns.

The higher synchronization must be factored in when programming the PWM ramp generator circuit. If the PWM ramp is interrupted by the SYNC pulse, a UVLO condition is declared and the PWM becomes disabled. Typically this is of concern under low-line conditions only. In any case,  $R_{\text{KFF}}$  needs to be adjusted for the higher switching frequency. In order to specify the correct value for  $R_{\text{KFF}}$  at the synchronizing frequency, calculate a 'dummy' value for  $R_T$  that would cause the oscillator to run at the synchronizing frequency. Do not use this value of  $R_T$  in the design.

$$R_{\text{T(dummy)}} = \left( \frac{1}{f_{\text{SYNC}} \times 17.82 \times 10^{-6}} - 23 \right) \text{k}\Omega$$

where:

- $f_{\text{SYNC}}$  is the synchronous frequency in kHz (10)

Use the value of  $R_{\text{T(dummy)}}$  to calculate the value for  $R_{\text{KFF}}$ .

$$R_{\text{KFF}} = (V_{\text{IN(min)}} - 3.5 \text{ V}) \times (65.27 \times R_{\text{T(dummy)}} + 1502) \Omega$$

where:

- $R_{\text{T(dummy)}}$  is in k $\Omega$  (11)

This value of  $R_{\text{KFF}}$  ensures that UVLO is not engaged when operating at the synchronization frequency.

## SELECTING THE INDUCTOR VALUE

The inductor value determines the magnitude of ripple current in the output capacitors as well as the load current at which the converter enters discontinuous mode. Too large an inductance results in lower ripple current but is physically larger for the same load current. Too small an inductance results in larger ripple currents and a greater number of (or more expensive output capacitors for) the same output ripple voltage requirement. A good compromise is to select the inductance value such that the converter doesn't enter discontinuous mode until the load approximated somewhere between 10% and 30% of the rated output. The inductance value is described in [Equation 12](#).

$$L = \frac{(V_{\text{IN}} - V_{\text{O}}) \times V_{\text{O}}}{V_{\text{IN}} \times \Delta I \times f_{\text{SW}}} \quad (\text{H})$$

where:

- $V_{\text{O}}$  is the output voltage
- $\Delta I$  is the peak-to-peak inductor current (12)

## CALCULATING THE OUTPUT CAPACITANCE

The output capacitance depends on the output ripple voltage requirement, output ripple current, as well as any output voltage deviation requirement during a load transient.

The output ripple voltage is a function of both the output capacitance and capacitor ESR. The worst case output ripple is described in [Equation 13](#).

$$\Delta V = \Delta I \left[ \text{ESR} + \left( \frac{1}{8 \times C_O \times f_{\text{SW}}} \right) \right] (V_{\text{P-P}}) \quad (13)$$

The output ripple voltage is typically between 90% and 95% due to the ESR component.

The output capacitance requirement typically increases in the presence of a load transient requirement. During a step load, the output capacitance must provide energy to the load (light to heavy load step) or absorb excess inductor energy (heavy-to-light load step) while maintaining the output voltage within acceptable limits. The amount of capacitance depends on the magnitude of the load step, the speed of the loop and the size of the inductor.

Stepping the load from a heavy load to a light load results in an output overshoot. Excess energy stored in the inductor must be absorbed by the output capacitance. The energy stored in the inductor is described in [Equation 14](#) and [Equation 15](#).

$$E_L = \frac{1}{2} \times L \times I^2 \quad (\text{J}) \quad (14)$$

where:

$$I^2 = \left[ (I_{\text{OH}})^2 - (I_{\text{OL}})^2 \right] \quad (\text{Amperes})^2$$

where:

- $I_{\text{OH}}$  is the output current under heavy load conditions
  - $I_{\text{OL}}$  is the output current under light load conditions
- (15)

Energy in the capacitor is given by the following equation:

$$E_C = \frac{1}{2} \times C \times V^2 \quad (\text{J}) \quad (16)$$

where:

$$V^2 = (V_f)^2 - (V_i)^2 \quad (\text{Volts}^2)$$

where:

- $V_f$  is the final peak capacitor voltage
  - $V_i$  is the initial capacitor voltage
- (17)

By substituting [Equation 15](#) into [Equation 14](#), substituting [Equation 17](#) into [Equation 16](#), setting [Equation 14](#) equal to [Equation 16](#) and solving for  $C_O$  yields the following equation.

$$C_O = \frac{L \times \left[ (I_{\text{OH}})^2 - (I_{\text{OL}})^2 \right]}{\left[ (V_f)^2 - (V_i)^2 \right]} \quad (\text{F}) \quad (18)$$

## Loop Compensation

Voltage-mode buck-type converters are typically compensated using Type III networks. Since the TPS40060 and TPS40061 use voltage feedforward control, the gain of the PWM modulator with voltage feedforward circuit must be included. The generic modulator gain is described in [Figure 8](#).

Duty cycle,  $D$ , varies from 0 to 1 as the control voltage,  $V_C$ , varies from the minimum ramp voltage to the maximum ramp voltage,  $V_S$ . Also, for a synchronous buck converter,  $D = V_O / V_{IN}$ . To get the control voltage to output voltage modulator gain in terms of the input voltage and ramp voltage,

$$D = \frac{V_O}{V_{IN}} = \frac{V_C}{V_S} \quad \text{or} \quad \frac{V_O}{V_C} = \frac{V_{IN}}{V_S} \quad (19)$$

With the voltage feedforward function, the ramp slope is proportional to the input voltage. Therefore, the moderator DC gain is independent of the change of input voltage. For the TPS40060 and TPS40061 the modulator dc gain is shown in Equation 20, with  $V_{IN(min)}$  as the minimum input voltage required to cause the ramp excursion to reach the maximum ramp amplitude of  $V_{RAMP}$ .

$$A_{MOD} = \left( \frac{V_{IN(min)}}{V_{RAMP}} \right) \quad \text{or} \quad A_{MOD(dB)} = 20 \times \log \left( \frac{V_{IN(min)}}{V_{RAMP}} \right) \quad (20)$$

### Calculate the Poles and Zeros

For a buck converter using voltage mode control there is a double pole due to the output L- $C_O$ . The double pole is located at the frequency calculated in Equation 21.

$$f_{LC} = \frac{1}{2\pi \times \sqrt{L \times C_O}} \quad (\text{Hz}) \quad (21)$$

There is also a zero created by the output capacitance,  $C_O$ , and its associated ESR. The ESR zero is located at the frequency calculated in Equation 22.

$$f_Z = \frac{1}{2\pi \times \text{ESR} \times C_O} \quad (\text{Hz}) \quad (22)$$

Calculate the value of  $R_{BIAS}$  to set the output voltage,  $V_O$ .

$$R_{BIAS} = \frac{0.7 \times R1}{V_O - 0.7} \Omega \quad (23)$$

The maximum crossover frequency (0 dB loop gain) is set by Equation 24.

$$f_C = \frac{f_{SW}}{4} \quad (\text{Hertz}) \quad (24)$$

Typically,  $f_C$  is selected to be close to the midpoint between the L- $C_O$  double pole and the ESR zero. At this frequency, the control to output gain has a  $-2$  slope ( $-40$  dB/decade), while the Type III topology has a  $+1$  slope ( $20$  dB/decade), resulting in an overall closed loop  $-1$  slope ( $-20$  dB/decade). Figure 9 shows the modulator gain, L-C filter, output capacitor ESR zero, and the resulting response to be compensated.

A Type III topology, shown in Figure 10, has two zero-pole pairs in addition to a pole at the origin. The gain and phase boost of a Type III topology is shown in Figure 11. The two zeros are used to compensate the L- $C_O$  double pole and provide phase boost. The double pole is used to compensate for the ESR zero and provide controlled gain roll-off. In many cases the second pole can be eliminated and the amplifier's gain roll-off used to roll-off the overall gain at higher frequencies.

PWM MODULATOR RELATIONSHIPS

Figure 8.

MODULATOR GAIN  
VS  
SWITCHING FREQUENCY

Figure 9.

Figure 10. Type III Compensation of Configuration

Figure 11. Type III Compensation Gain and Phase

The poles and zeros for a type III network are described in Equation 25.

$$f_{z1} = \frac{1}{2\pi \times R2 \times C1} \text{ (Hz)} \quad f_{z2} = \frac{1}{2\pi \times R1 \times C3} \text{ (Hz)} \quad (25)$$

$$f_{p1} = \frac{1}{2\pi \times R2 \times C2} \text{ (Hz)} \quad f_{p2} = \frac{1}{2\pi \times R3 \times C3} \text{ (Hz)}$$

The value of R1 is somewhat arbitrary, but influences other component values. A value between 50kΩ and 100kΩ usually yields reasonable values.

The unity gain frequency is described in Equation 26.

$$f_c = \frac{1}{2\pi \times R1 \times C2 \times G} \text{ (Hertz)}$$

where

- G is the reciprocal of the modulator gain at  $f_c$  (26)

The modulator gain as a function of frequency at  $f_C$ , is described in [Equation 27](#).

$$AMOD(f) = AMOD \times \left( \frac{f_{LC}}{f_C} \right)^2 \quad \text{and} \quad G = \frac{1}{AMOD(f)} \quad (27)$$

Care must be taken not to load down the output of the error amplifier with the feedback resistor, R2, that is too small. The error amplifier has a finite output source and sink current which must be considered when sizing R2. Too small a value does not allow the output to swing over its full range.

$$R2_{(MIN)} = \frac{V_{C(max)}}{I_{SOURCE(min)}} (\Omega) = \frac{3.45 V}{2.0 mA} = 1.725 k\Omega \quad (28)$$

### dv/dt INDUCED TURN-ON

MOSFETs are susceptible to dv/dt turn-on particularly in high-voltage ( $V_{DS}$ ) applications. The turn-on is caused by the capacitor divider that is formed by  $C_{GD}$  and  $C_{GS}$ . High dv/dt conditions and drain-to-source voltage, on the MOSFET causes current flow through  $C_{GD}$  and causes the gate-to-source voltage to rise. If the gate-to-source voltage rises above the MOSFET threshold voltage, the MOSFET turns on, resulting in large shoot-through currents. Therefore the SR MOSFET should be chosen so that the  $C_{GD}$  capacitance is smaller than the  $C_{GS}$  capacitance. A 2- $\Omega$  to 5- $\Omega$  resistor in the upper MOSFET gate lead shapes the turn-on and dv/dt of the SW node and helps reduce the induced turn-on.

### HIGH-SIDE MOSFET POWER DISSIPATION

The power dissipated in the external high-side MOSFET is comprised of conduction and switching losses. The conduction losses are a function of the  $I_{RMS}$  current through the MOSFET and the  $R_{DS(on)}$  of the MOSFET. The high-side MOSFET conduction losses are defined by [Equation 29](#).

$$P_{COND} = (I_{RMS})^2 \times R_{DS(on)} \times \left( 1 + TC_R \times [T_J - 25^\circ C] \right) \quad (W) \quad (29)$$

where:

- $TC_R$  is the temperature coefficient of the MOSFET  $R_{DS(on)}$

The  $TC_R$  varies depending on MOSFET technology and manufacturer but is typically ranges between 3500 ppm/ $^\circ C$  and 1000 ppm/ $^\circ C$ .

The  $I_{RMS}$  current for the high side MOSFET is described in [Equation 30](#).

$$I_{RMS} = I_O \times \sqrt{d} \quad (\text{Amperes}_{RMS}) \quad (30)$$

The switching losses for the high-side MOSFET are described in [Equation 31](#).

$$P_{SW(fsw)} = (V_{IN} \times I_{OUT} \times t_{SW}) \times f_{SW} \quad (\text{Watts}) \quad (31)$$

where:

- $I_O$  is the DC output current
- $t_{SW}$  is the switching rise time, typically < 20 ns
- $f_{SW}$  is the switching frequency

Typical switching waveforms are shown in [Figure 12](#).

Figure 12. Inductor Current and SW Node Waveforms

The maximum allowable power dissipation in the MOSFET is determined by the following equation.

$$P_T = \frac{(T_J - T_A)}{\theta_{JA}} \quad (W) \quad (32)$$

where:

$$P_T = P_{COND} + P_{SW(f_{sw})} \quad (W) \quad (33)$$

and  $\theta_{JA}$  is the package thermal impedance.

### SYNCHRONOUS RECTIFIER MOSFET POWER DISSIPATION

The power dissipated in the synchronous rectifier MOSFET is comprised of three components:  $R_{DS(on)}$  conduction losses, body diode conduction losses, and reverse recovery losses.  $R_{DS(on)}$  conduction losses can be found using Equation 29 and the RMS current through the synchronous rectifier MOSFET is described in Equation 34.

$$I_{RMS} = I_O \times \sqrt{1 - d} \quad (A_{RMS}) \quad (34)$$

The body-diode conduction losses are due to forward conduction of the body diode during the anti-cross conduction delay time. The body diode conduction losses are described by Equation 35.

$$P_{DC} = 2 \times I_O \times V_F \times t_{DELAY} \times f_{SW} \quad (W)$$

where:

- $V_F$  is the body diode forward voltage
- $t_{DELAY}$  is the delay time just before the SW node rises

The 2-multiplier is used because the body-diode conducts twice during each cycle (once on the rising edge and once on the falling edge)

The reverse recovery losses are due to the time it takes for the body diode to recovery from a forward bias to a reverse blocking state. The reverse recovery losses are described in Equation 36.

$$P_{RR} = 0.5 \times Q_{RR} \times V_{IN} \times f_{SW} \quad (W)$$

where:

- $Q_{RR}$  is the reverse recovery charge of the body diode

The total synchronous rectifier MOSFET power dissipation is described in Equation 37.

$$P_{SR} = P_{DC} + P_{RR} + P_{COND} \quad (W) \quad (37)$$

## TPS40060/TPS40061 POWER DISSIPATION

The power dissipation in the TPS40060 and TPS40061 is largely dependent on the MOSFET driver currents and the input voltage. The driver current is proportional to the total gate charge,  $Q_g$ , of the external MOSFETs. Driver power (neglecting external gate resistance, (refer to the second reference in the [REFERENCES](#) section) can be calculated from [Equation 38](#).

$$P_D = Q_g \times V_{DR} \times f_{SW} \quad (\text{W / driver}) \quad (38)$$

And the total power dissipation in the device, assuming MOSFETs with similar gate charges for both the high-side and synchronous rectifier is described in [Equation 39](#).

$$P_T = \left( \frac{2 \times P_D}{V_{DR}} + I_Q \right) \times V_{IN} \quad (\text{W}) \quad (39)$$

or

$$P_T = \left[ (2 \times Q_g \times f_{SW}) + I_Q \right] \times V_{IN} \quad (\text{W})$$

where:

- $I_Q$  is the quiescent operating current (neglecting drivers) (40)

The maximum power capability of the device's PowerPad package is dependent on the layout as well as air flow. The thermal impedance from junction to air, assuming 2 oz. copper trace and thermal pad with solder and no air flow.

$$\Theta_{JA} = 36.51^\circ\text{C/W}$$

The maximum allowable package power dissipation is related to ambient temperature by [Equation 36](#). Substituting [Equation 32](#) into [Equation 40](#) and solving for  $f_{SW}$  yields the maximum operating frequency for the TPS40060 and TPS40061. The result is:

$$f_{SW} = \frac{\left( \left[ \frac{(T_J - T_A)}{(\Theta_{JA} \times V_{IN})} \right] - I_Q \right)}{(2 \times Q_g)} \quad (\text{Hz}) \quad (41)$$

## LAYOUT CONSIDERATIONS

### THE PowerPAD™ PACKAGE

The PowerPAD package provides low thermal impedance for heat removal from the device. The PowerPAD derives its name and low thermal impedance from the large bonding pad on the bottom of the device. For maximum thermal performance, the circuit board must have an area of solder-tinned-copper underneath the package. The dimensions of this area depends on the size of the PowerPAD package. For a 16-pin TSSOP (PWP) package the dimensions of the circuit board pad are 5 mm x 3.4 mm. The dimensions of the package pad are shown in Figure 13.

Thermal vias connect this area to internal or external copper planes and should have a drill diameter sufficiently small so that the via hole is effectively plugged when the barrel of the via is plated with copper. This plug is needed to prevent wicking the solder away from the interface between the package body and the solder-tinned area under the device during solder reflow. Drill diameters of 0.33 mm (13 mils) works well when 1-oz copper is plated at the surface of the board while simultaneously plating the barrel of the via. If the thermal vias are not plugged when the copper plating is performed, then a solder mask material should be used to cap the vias with a diameter equal to the via diameter of 0.1 mm minimum. This capping prevents the solder from being wicked through the thermal vias and potentially creating a solder void under the package. Refer to *PowerPAD Thermally Enhanced Package* (see REFERENCES section) for more information on the PowerPAD package.

Figure 13. PowerPAD Dimensions

### MOSFET PACKAGING

MOSFET package selection depends on MOSFET power dissipation and the projected operating conditions. In general, for a surface-mount applications, the DPAK style package provides the lowest thermal impedance ( $\theta_{JA}$ ) and, therefore, the highest power dissipation capability. However, the effectiveness of the DPAK depends on proper layout and thermal management. The  $\theta_{JA}$  specified in the MOSFET data sheet refers to a given copper area and thickness. In most cases, a thermal impedance of 40°C/W requires one square inch of 2-ounce copper on a G-10/FR-4 board. Lower thermal impedances can be achieved at the expense of board area. Please refer to the selected MOSFET's data sheet for more information regarding proper mounting.

### GROUNDING AND CIRCUIT LAYOUT CONSIDERATIONS

The device provides separate signal ground (SGND) and power ground (PGND) pins. It is important that circuit grounds are properly separated. Each ground should consist of a plane to minimize its impedance if possible. The high power *noisy* circuits such as the output, synchronous rectifier, MOSFET driver decoupling capacitor (BP10), and the input capacitor should be connected to PGND plane at the input capacitor.

Sensitive nodes such as the FB resistor divider,  $R_T$ , and ILIM should be connected to the SGND plane. The SGND plane should only make a single point connection to the PGND plane.

Component placement should ensure that bypass capacitors (BP10, BP5, and BPN10) are located as close as possible to their respective power and ground pins. Also, sensitive circuits such as FB, RT and ILIM should not be located near high dv/dt nodes such as HDRV, LDRV, BPN10, and the switch node (SW).

## DESIGN EXAMPLE

- Input voltage: 18 V<sub>DC</sub> to 55 V<sub>DC</sub>
- Output voltage: 3.3 V ±2%
- Output current: 5 A (maximum, steady-state), 7 A (surge, 10-ms duration, 10% duty cycle maximum)
- Output ripple: 33 mV<sub>P-P</sub> at 5 A
- Output load response: 0.3 V => 10% to 90% step load change
- Operating temperature: –40°C to 85°C
- f<sub>SW</sub> = 130 kHz

### 1. Calculate maximum and minimum duty cycles

$$d_{\text{MIN}} = \frac{V_{\text{O}(\text{min})}}{V_{\text{IN}(\text{max})}} = 0.0588 \quad d_{\text{MAX}} = \frac{V_{\text{O}(\text{max})}}{V_{\text{IN}(\text{min})}} = 0.187 \quad (42)$$

### 2. Select switching frequency

The switching frequency is based on the minimum duty cycle ratio and the propagation delay of the current limit comparator. In order to maintain current limit capability, the on time of the upper MOSFET, t<sub>ON</sub>, must be greater than 330 ns (see [Electrical Characteristics](#) table). Therefore

$$\frac{V_{\text{O}(\text{min})}}{V_{\text{IN}(\text{max})}} = \frac{t_{\text{ON}}}{T_{\text{SW}}} \quad \text{or} \quad (43)$$

$$\frac{1}{T_{\text{SW}}} = f_{\text{SW}} = \left[ \frac{\left( \frac{V_{\text{O}(\text{min})}}{V_{\text{IN}(\text{max})}} \right)}{T_{\text{ON}}} \right] \quad (44)$$

Using 400 ns to provide margin,

$$f_{\text{SW}} = \frac{0.0588}{400 \text{ ns}} = 147 \text{ kHz} \quad (45)$$

Since the oscillator can vary by 10%, decrease f<sub>SW</sub>, by 10%

$$f_{\text{SW}} = 0.9 \times 147 \text{ kHz} = 130 \text{ kHz}$$

and therefore choose a frequency of 130 kHz.

### 3. Select ΔI

In this case ΔI is chosen so that the converter enters discontinuous mode at 20% of nominal load.

$$\Delta I = I_{\text{O}} \times 2 \times 0.2 = 5 \times 2 \times 0.2 = 2.0 \text{ A} \quad (46)$$

### 4. Calculate the high-side MOSFET power losses

Power losses in the high-side MOSFET (Si9407AGY) at 55-V<sub>IN</sub> where switching losses dominate can be calculated from [Equation 46](#) through [Equation 49](#).

$$I_{\text{RMS}} = I_{\text{O}} \times \sqrt{d} = 5 \times \sqrt{0.0588} = 1.2 \text{ A} \quad (47)$$

substituting [Equation 47](#) into [Equation 29](#) yields

$$P_{\text{COND}} = 1.2^2 \times 0.12 \times (1 + 0.007 \times (150 - 25)) = 0.324 \text{ W} \quad (48)$$

and from [Equation 31](#), the switching losses can be determined.

$$P_{\text{SW}(f_{\text{sw}})} = (V_{\text{IN}} \times I_{\text{O}} \times t_{\text{SW}}) \times f_{\text{SW}} = 55 \text{ V} \times 5 \text{ A} \times 20 \text{ ns} \times 130 \text{ kHz} = 0.715 \text{ W} \quad (49)$$

The MOSFET junction temperature can be found by substituting [Equation 33](#) into [Equation 32](#)

$$T_J = (P_{\text{COND}} + P_{\text{SW}}) \times \theta_{\text{JA}} + T_A = (0.324 + 0.715) \times 40 + 85 = 127^\circ\text{C} \quad (50)$$

## 5. Calculate synchronous rectifier losses

The synchronous rectifier MOSFET has two loss components, conduction, and diode reverse recovery losses. The conduction losses are due to  $I_{\text{RMS}}$  losses as well as body diode conduction losses during the dead time associated with the anti-cross conduction delay.

The  $I_{\text{RMS}}$  current through the synchronous rectifier from [Equation 51](#)

$$I_{\text{RMS}} = I_O \times \sqrt{1 - d} = 5 \times \sqrt{1 - 0.0588} = 4.85 \text{ A}_{\text{RMS}} \quad (51)$$

The synchronous MOSFET conduction loss from [Equation 29](#) is:

$$P_{\text{COND}} = 4.85^2 \times 0.011 \times (1 + 0.007(150 - 25)) = 0.485 \text{ W} \quad (52)$$

The body diode conduction loss from [Equation 35](#) is:

$$P_{\text{DC}} = 2 \times I_O \times V_{\text{FD}} \times t_{\text{DELAY}} \times f_{\text{SW}} = 2 \times 5 \text{ A} \times 0.8 \text{ V} \times 50 \text{ ns} \times 130 \text{ kHz} = 0.052 \text{ W} \quad (53)$$

The body diode reverse recovery loss from [Equation 36](#) is:

$$P_{\text{RR}} = 0.5 \times Q_{\text{RR}} \times V_{\text{IN}} \times f_{\text{SW}} = 0.5 \times 30 \text{ nC} \times 55 \text{ V} \times 130 \text{ kHz} = 0.107 \text{ W} \quad (54)$$

The total power dissipated in the synchronous rectifier MOSFET from [Equation 37](#) is:

$$P_{\text{SR}} = P_{\text{RR}} + P_{\text{COND}} + P_{\text{DC}} = 0.107 + 0.485 + 0.052 = 0.644 \text{ W} \quad (55)$$

The junction temperature of the synchronous rectifier at  $85^\circ\text{C}$  is:

$$T_J = P_{\text{SR}} \times \theta_{\text{JA}} + T_A = (0.644) \times 40 + 85 = 111^\circ\text{C} \quad (56)$$

In typical applications, paralleling the synchronous rectifier MOSFET with a Schottky rectifier increases the overall converter efficiency by approximately 2% due to the lower power dissipation during the body diode conduction and reverse recovery periods.

## 6. Calculate the Inductor Value

The inductor value is calculated from [Equation 12](#).

$$L = \frac{(55 - 3.3) \times 3.3}{55 \times 2 \times 130 \text{ kHz}} = 11.9 \mu\text{H} \quad (57)$$

A standard inductor value of 10- $\mu\text{H}$  is chosen. A Coev DXM1306-10RO or Panasonic ETQPF102HFA could be used.

## 7. Setting the switching frequency

The clock frequency is set with a resistor ( $R_T$ ) from the RT pin to ground. The value of  $R_T$  can be derived from following [Equation 58](#), with  $f_{\text{SW}}$  in kHz.

$$R_T = \left( \frac{1}{f_{\text{SW}} \times 17.82 \text{ E} - 06} - 23 \right) \text{ k}\Omega = 408 \text{ k}\Omega, \text{ use } 412 \text{ k}\Omega \quad (58)$$

## 8. Programming the Ramp Generator Circuit

The PWM ramp is programmed through a resistor ( $R_{\text{KFF}}$ ) from the KFF pin to  $V_{\text{IN}}$ . The ramp generator also controls the input UVLO voltage. For an undervoltage level of 14.4V (20% below the 18  $V_{\text{IN(min)}}$ ),  $R_{\text{KFF}}$  is calculated in [Equation 59](#).

$$R_{\text{KFF}} = (80\% \times V_{\text{IN(min)}} - 3.5)(65.27 \times R_T + 1502) \Omega = 309 \text{ k}\Omega, \text{ use } 301 \text{ k}\Omega \quad (59)$$

## 9. Calculating the Output Capacitance ( $C_O$ )

In this example, the output capacitance is determined by the load response requirement of  $\Delta V = 0.3$  V for a 1 A to 5 A step load.  $C_O$  can be calculated using [Equation 18](#).

$$C_O = \frac{10 \mu\text{H} \times (5^2 - 1^2)}{(3.3^2 - 3.0^2)} = 127 \mu\text{F} \quad (60)$$

Using [Equation 13](#) calculate the ESR required to meet the output ripple requirements.

$$33 \text{ mV} = 2.0 \left( \text{ESR} + \frac{1}{8 \times 127 \mu\text{F} \times 130 \text{ kHz}} \right) \quad (61)$$

$$\text{ESR} = 8.9 \text{ m}\Omega$$

In order to get the required ESR, the capacitance needs to be greater than the 127- $\mu\text{F}$  calculated. For example, a single Panasonic SP capacitor, 180- $\mu\text{F}$  with ESR of 12 m $\Omega$  can be used. Re-calculating the ESR required with the new value of 180- $\mu\text{F}$  is shown in [Equation 62](#).

$$33 \text{ mV} = 2.0 \left( \text{ESR} + \frac{1}{8 \times 180 \mu\text{F} \times 130 \text{ kHz}} \right) \quad (62)$$

$$\text{ESR} = 11.1 \text{ m}\Omega$$

## 10. Calculate the Soft-Start Capacitor ( $C_{SS}$ )

This design requires a soft-start time ( $t_{\text{START}}$ ) of 1 ms.  $C_{SS}$  is calculated in [Equation 63](#).

$$C_{SS} = \frac{2.3 \mu\text{A}}{0.7 \text{ V}} \times 1 \text{ ms} = 3.28 \text{ nF} = 3300 \text{ pF} \quad (63)$$

## 11. Calculate the Current Limit Resistor ( $R_{\text{ILIM}}$ )

The current limit set point depends on  $t_{\text{START}}$ ,  $V_O$ ,  $C_O$  and  $I_{\text{LOAD}}$  at start up as shown in [Equation 7](#).

$$I_{\text{LIM}} > \frac{180 \mu\text{F} \times 3.3}{1 \text{ m}} + 7.0 = 7.6 \text{ A} \quad (64)$$

Set  $I_{\text{LIM}}$  for 10.0 A minimum, then from [Equation 7](#)

$$R_{\text{ILIM}} = \frac{10 \times 0.14}{I_{\text{SINK}}} + \frac{V_{\text{OS}}}{I_{\text{SINK}}} \Omega = \frac{10 \times 0.14}{8.3 \mu\text{A}} + \frac{(50 \text{ mV})}{8.3 \mu\text{A}} \Omega = 175 \text{ k}\Omega = 174 \text{ k}\Omega \quad (65)$$

## 12. Calculate Loop Compensation Values

Calculate the DC modulator gain ( $A_{\text{MOD}}$ ) from [Equation 20](#).

$$A_{\text{MOD}} = \frac{18}{2} = 9 \quad (66)$$

$$A_{\text{MOD(dB)}} = 20 \times \log(9) = 19 \text{ dB} \quad (67)$$

Calculate the output poles and zeros from [Equation 21](#) and [Equation 22](#) of the L-C filter.

$$f_{\text{LC}} = \frac{1}{2\pi \sqrt{10 \mu\text{H} \times 180 \mu\text{F}}} = 3.7 \text{ kHz} \quad (68)$$

and

$$f_z = \frac{1}{2\pi \times 0.012 \times 180 \mu\text{F}} = 74 \text{ kHz} \quad (69)$$

Select the close-loop 0 dB crossover frequency,  $f_c$ . For this example  $f_c = 10$  kHz.

Select the double zero location for the Type III compensation network at the output filter double pole at 3.7 kHz.

Select the double pole location for the Type III compensation network at the output capacitor ESR zero at 73.7 kHz.

The amplifier gain at the crossover frequency of 10 kHz is determined by the reciprocal of the modulator gain  $A_{MOD}$  at the crossover frequency from Equation 27.

$$A_{MOD(f)} = A_{MOD} \times \left( \frac{f_{LC}}{f_C} \right)^2 = 9 \times \left( \frac{3.7 \text{ kHz}}{10 \text{ kHz}} \right)^2 = 1.23 \quad (70)$$

And also from Equation 27.

$$G = \frac{1}{A_{MOD(f)}} = \frac{1}{1.23} = 0.81 \quad (71)$$

Choose  $R_1 = 100 \text{ k}\Omega$

The poles and zeros for a Type III network are described in Equation 25 and Equation 26.

$$f_{Z2} = \frac{1}{2\pi \times R_1 \times C_3} \therefore C_3 = \frac{1}{2\pi \times 100 \text{ k}\Omega \times 3.7 \text{ kHz}} = 430 \text{ pF, choose } 470 \text{ pF} \quad (72)$$

$$f_{P2} = \frac{1}{2\pi \times R_3 \times C_3} \therefore R_3 = \frac{1}{2\pi \times 470 \text{ pF} \times 73.7 \text{ kHz}} = 4.59 \text{ k}\Omega, \text{ choose } 4.64 \text{ k}\Omega \quad (73)$$

$$f_C = \frac{1}{2\pi \times R_1 \times C_2 \times G} \therefore C_2 = \frac{1}{2\pi \times 100 \text{ k}\Omega \times 0.81 \times 10 \text{ kHz}} = 196 \text{ pF, choose } 220 \text{ pF} \quad (74)$$

$$f_{P1} = \frac{1}{2\pi \times R_2 \times C_2} \therefore R_2 = \frac{1}{2\pi \times 220 \text{ pF} \times 73.7 \text{ kHz}} = 9.82 \text{ k}\Omega, \text{ choose } 10 \text{ k}\Omega \quad (75)$$

$$f_{Z1} = \frac{1}{2\pi \times R_2 \times C_1} \therefore C_1 = \frac{1}{2\pi \times 10 \text{ k}\Omega \times 3.7 \text{ kHz}} = 4301 \text{ pF, choose } 3900 \text{ pF} \quad (76)$$

Calculate the value of  $R_{BIAS}$  from Equation 23 with  $R_1 = 100 \text{ k}\Omega$ .

$$R_{BIAS} = \frac{0.7 \text{ V} \times R_1}{V_O - 0.7 \text{ V}} = \frac{0.7 \text{ V} \times 100 \text{ k}\Omega}{3.3 \text{ V} - 0.7 \text{ V}} = 26.9 \text{ k}\Omega, \text{ choose } 26.7 \text{ k}\Omega \quad (77)$$

## CALCULATING THE BPN10 AND BP10V BYPASS CAPACITANCE

The size of the bypass capacitor depends on the total gate charge of the MOSFET being used and the amount of droop allowed on the bypass capacitor. The BPN10 capacitance, allowing for a 0.5-V droop on the BPN10 pin from Equation 8 is shown in Equation 78.

$$C_{BPN10} = \frac{Q_g}{\Delta V} = \frac{30 \text{ nC}}{0.5} = 60 \text{ nF} \quad (78)$$

and the BP10V capacitance from Equation 9 is shown in Equation 79.

$$C_{BP10V} = \frac{Q_{gSR}}{\Delta V} = \frac{57 \text{ nC}}{0.5} = 114 \text{ nF} \quad (79)$$

For this application, a 0.1- $\mu\text{F}$  capacitor was used for the BPN10V and a 1.0- $\mu\text{F}$  was used for the BP10V bypass capacitor. Figure 14 shows component selection for the 18-V through 55-V to 3.3-V at 5-A dc-to-dc converter specified in the design example.

## GATE DRIVE CONFIGURATION

Due to the possibility of  $dv/dt$  induced turn-on from the fast MOSFET switching times, high  $V_{DS}$  voltage and low gate threshold voltage of the Si4470, the design includes a 2- $\Omega$  in the gate lead of the upper MOSFET. The resistor can be used to shape the low-to-high transition of the Switch node and reduce the tendency of  $dv/dt$ -induced turn on.

## REVISION HISTORY

Changes from Revision E (June 2006) to Revision F	Page
• Changed reference to Figure 13, PowerPad Dimensions, to Figure 14, Design Example, 48 V to 3.3 V at 5 A dc-to-dc Converter .....	7
• Changed both ( $C_{SS} - 0.85\text{ V}$ ) voltages to ( $V_{CSS} - 0.85\text{ V}$ ) in Programming Soft Start .....	10
• Changed <i>turn-on</i> ( $I_L$ ) to <i>start-up</i> ( $I_{LOAD}$ ) in the third paragraph of <a href="#">Programming Current Limit</a> section. ....	11
• Changed first instance of BPN10 to BP10 in respective section title. ....	11
• Added high-side before MOSFET in the <a href="#">Calculating the BP10 and BP10V Bypass Capacitor</a> section .....	12
• Changed <i>HDRV signal goes high</i> to <i>...goes low</i> in the <a href="#">Synchronizing to an External Supply</a> section .....	13
• Added equation definition for $f_{SYNC}$ to <a href="#">Equation 10</a> .....	13
• Deleted k from $K\Omega$ at the end of equation <a href="#">Equation 11</a> .....	13
• Added (dummy) to $R_T$ in <a href="#">Equation 11</a> definition .....	13
• Changed sequence of equation substitutions from: Equation 14 into Equation 13, Equation 16 into Equation 15, Equation 13 equal to Equation 15, to: Equation 15 into Equation 14, Equation 17 into Equation 16, Equation 14 equal to Equation 16 .....	14
• Added generic before modulator gain in first paragraph of the <a href="#">Loop Compensation</a> section .....	14
• Deleted <i>with <math>V_{IN}</math> being the minimum input voltage required to cause the ramp excursion to cover the entire switching period.</i> from first paragraph of the <a href="#">Loop Compensation</a> section .....	14
• Deleted previous Equation 19, which was $A_{MOD} = V_{IN} / V_S$ or $A_{MOD(db)} = 20 \times \log(V_{IN} / V_S)$ .....	14
• Changed figure reference for modulator gain in the <a href="#">Loop Compensation</a> from Figure 6 ( <i>Typical Current Limit Protection Waveforms</i> ) to Figure 8 ( <i>PWM MODULATOR RELATIONSHIPS</i> ) .....	14
• Added modulator DC gain and new Equation 20 to <a href="#">Loop Compensation</a> section .....	15
• Changed $V_{OUT}$ to $V_O$ in sentence before and in <a href="#">Equation 23</a> .....	15
• Changed calculated in to set by in sentence before <a href="#">Equation 24</a> .....	15
• Changed $V_{IN} / V_S$ to $V_{IN(min)} / V_{RAMP}$ in the Modulator Gain vs Switching Frequency graph .....	15
• Changed the $TC_R$ minimum value from 0.0035 to 3500 and the maximum from 0.010 to 10000 in the second paragraph of the <a href="#">High-Side MOSFET Power Dissipation</a> section .....	17
• Changed $V_{DD}$ to $V_{IN}$ in <a href="#">Equation 41</a> .....	19
• Changed PowerPAD Dimensions to include x and y axis values .....	20
• Added high-side MOSFET to step four title .....	22
• Changed reference to substituting Equation 30 to Equation 47 .....	22
• Deleted $I_{RMS}^2 \times R_{DS(ON)}$ from synchronous MOSFET conduction equation .....	23
• Changed synchronous MOSFET conduction equation equals value from 0.10 to 0.485 .....	23
• Changed body diode conduction equation values: 100 ns to 50 ns and 0.104 W to 0.052 W .....	23
• Changed power dissipation equation values: 0.1 to 0.485, 0.104 to 0.052, 0.311 W to 0.644 W .....	23
• Changed junction temperature equation values: (0.311) to 0.644, 97°C to 111°C .....	23
• Changed Step 6 reference to Equation 11 to Equation 12 .....	23
• Changed inductor value equation in Step 6: replaced value of 48 with 55 and 11.8 with 11.9 .....	23
• Changed $R_{KFF}$ equation values in Step 8: 133.7 to 309 k $\Omega$ , 133 to 301 k $\Omega$ .....	23
• Added 80% $\times$ before $V_{IN(min)}$ in $R_{KFF}$ equation in Step 8 .....	23
• Changed first ESR value in Step 9 from 12.7 to 8.9 m $\Omega$ .....	24
• Changed second ESR value in Step 9 from 13.8 to 11.1 m $\Omega$ .....	24
• Changed DC modulator gain values in both equations: 10 to 18, 5 to 9; (5.0) to 9, 14 to 19 dB .....	24
• Changed AMOD crossover frequency equation values: 5 to 9, 0.68 to 1.23 .....	25
• Changed gain (G) equation values: 0.68 to 1.23, 1.46 to 0.81 .....	25
• Changed poles and zeros equation values: Equation 73, 73.3 to 73.7 kHz, 4.62 to 4.59 k $\Omega$ ; Equation 74, 3.29 to 0.81, 1.46 to 10 kHz, 109 to 196 pF, 100 to 220 pF; Equation 75, 100 to 200 pF, 73.3 to 73.7 kHz, 21.7 to 9.82 k $\Omega$ ,	

---

21.5 to 10 k $\Omega$ ; Equation 76, 21.5 to 10 k $\Omega$ , 2000 to 4301 pF, 1800 to 3900 pF .....	25
• Changed Design Example graphic to include new values from equation: 133 to 301 k $\Omega$ , 1800 to 3900 pF, 21.5 to 10 k $\Omega$ , 100 to 220 pF. Si9470 to Si9407 .....	25
• Added link references to hard-coded references throughout document .....	26

---

(1) The marketing status values are defined as follows:

**ACTIVE:** Product device recommended for new designs.

**LIFEBUY:** TI has announced that the device will be discontinued, and a lifetime-buy period is in effect.

**NRND:** Not recommended for new designs. Device is in production to support existing customers, but TI does not recommend using this part in a new design.

**PREVIEW:** Device has been announced but is not in production. Samples may or may not be available.

**OBSOLETE:** TI has discontinued the production of the device.

(2) Eco Plan - The planned eco-friendly classification: Pb-Free (RoHS), Pb-Free (RoHS Exempt), or Green (RoHS & no Sb/Br) - please check <http://www.ti.com/productcontent> for the latest availability information and additional product content details.

**TBD:** The Pb-Free/Green conversion plan has not been defined.

**Pb-Free (RoHS):** TI's terms "Lead-Free" or "Pb-Free" mean semiconductor products that are compatible with the current RoHS requirements for all 6 substances, including the requirement that lead not exceed 0.1% by weight in homogeneous materials. Where designed to be soldered at high temperatures, TI Pb-Free products are suitable for use in specified lead-free processes.

**Pb-Free (RoHS Exempt):** This component has a RoHS exemption for either 1) lead-based flip-chip solder bumps used between the die and package, or 2) lead-based die adhesive used between the die and leadframe. The component is otherwise considered Pb-Free (RoHS compatible) as defined above.

**Green (RoHS & no Sb/Br):** TI defines "Green" to mean Pb-Free (RoHS compatible), and free of Bromine (Br) and Antimony (Sb) based flame retardants (Br or Sb do not exceed 0.1% by weight in homogeneous material)

(3) MSL, Peak Temp. -- The Moisture Sensitivity Level rating according to the JEDEC industry standard classifications, and peak solder temperature.

<sup>(4)</sup> Multiple Top-Side Markings will be inside parentheses. Only one Top-Side Marking contained in parentheses and separated by a "~" will appear on a device. If a line is indented then it is a continuation of the previous line and the two combined represent the entire Top-Side Marking for that device.

**Important Information and Disclaimer:** The information provided on this page represents TI's knowledge and belief as of the date that it is provided. TI bases its knowledge and belief on information provided by third parties, and makes no representation or warranty as to the accuracy of such information. Efforts are underway to better integrate information from third parties. TI has taken and continues to take reasonable steps to provide representative and accurate information but may not have conducted destructive testing or chemical analysis on incoming materials and chemicals. TI and TI suppliers consider certain information to be proprietary, and thus CAS numbers and other limited information may not be available for release.

In no event shall TI's liability arising out of such information exceed the total purchase price of the TI part(s) at issue in this document sold by TI to Customer on an annual basis.

## THERMAL PAD MECHANICAL DATA

### PWP (R-PDSO-G16) PowerPAD™ SMALL PLASTIC OUTLINE

#### THERMAL INFORMATION

This PowerPAD™ package incorporates an exposed thermal pad that is designed to be attached to a printed circuit board (PCB). The thermal pad must be soldered directly to the PCB. After soldering, the PCB can be used as a heatsink. In addition, through the use of thermal vias, the thermal pad can be attached directly to the appropriate copper plane shown in the electrical schematic for the device, or alternatively, can be attached to a special heatsink structure designed into the PCB. This design optimizes the heat transfer from the integrated circuit (IC).

For additional information on the PowerPAD package and how to take advantage of its heat dissipating abilities, refer to Technical Brief, PowerPAD Thermally Enhanced Package, Texas Instruments Literature No. SLMA002 and Application Brief, PowerPAD Made Easy, Texas Instruments Literature No. SLMA004. Both documents are available at [www.ti.com](http://www.ti.com).

The exposed thermal pad dimensions for this package are shown in the following illustration.

PowerPAD™ PLASTIC SMALL OUTLINE

- NOTES:
- A. All linear dimensions are in millimeters.
  - B. This drawing is subject to change without notice.
  - C. Customers should place a note on the circuit board fabrication drawing not to alter the center solder mask defined pad.
  - D. This package is designed to be soldered to a thermal pad on the board. Refer to Technical Brief, PowerPad Thermally Enhanced Package, Texas Instruments Literature No. SLMA002, SLMA004, and also the Product Data Sheets for specific thermal information, via requirements, and recommended board layout. These documents are available at [www.ti.com](http://www.ti.com) <<http://www.ti.com>>. Publication IPC-7351 is recommended for alternate designs.
  - E. Laser cutting apertures with trapezoidal walls and also rounding corners will offer better paste release. Customers should contact their board assembly site for stencil design recommendations. Example stencil design based on a 50% volumetric metal load solder paste. Refer to IPC-7525 for other stencil recommendations.
  - F. Customers should contact their board fabrication site for solder mask tolerances between and around signal pads.

## IMPORTANT NOTICE

Texas Instruments Incorporated and its subsidiaries (TI) reserve the right to make corrections, enhancements, improvements and other changes to its semiconductor products and services per JESD46, latest issue, and to discontinue any product or service per JESD48, latest issue. Buyers should obtain the latest relevant information before placing orders and should verify that such information is current and complete. All semiconductor products (also referred to herein as "components") are sold subject to TI's terms and conditions of sale supplied at the time of order acknowledgment.

TI warrants performance of its components to the specifications applicable at the time of sale, in accordance with the warranty in TI's terms and conditions of sale of semiconductor products. Testing and other quality control techniques are used to the extent TI deems necessary to support this warranty. Except where mandated by applicable law, testing of all parameters of each component is not necessarily performed.

TI assumes no liability for applications assistance or the design of Buyers' products. Buyers are responsible for their products and applications using TI components. To minimize the risks associated with Buyers' products and applications, Buyers should provide adequate design and operating safeguards.

TI does not warrant or represent that any license, either express or implied, is granted under any patent right, copyright, mask work right, or other intellectual property right relating to any combination, machine, or process in which TI components or services are used. Information published by TI regarding third-party products or services does not constitute a license to use such products or services or a warranty or endorsement thereof. Use of such information may require a license from a third party under the patents or other intellectual property of the third party, or a license from TI under the patents or other intellectual property of TI.

Reproduction of significant portions of TI information in TI data books or data sheets is permissible only if reproduction is without alteration and is accompanied by all associated warranties, conditions, limitations, and notices. TI is not responsible or liable for such altered documentation. Information of third parties may be subject to additional restrictions.

Resale of TI components or services with statements different from or beyond the parameters stated by TI for that component or service voids all express and any implied warranties for the associated TI component or service and is an unfair and deceptive business practice. TI is not responsible or liable for any such statements.

Buyer acknowledges and agrees that it is solely responsible for compliance with all legal, regulatory and safety-related requirements concerning its products, and any use of TI components in its applications, notwithstanding any applications-related information or support that may be provided by TI. Buyer represents and agrees that it has all the necessary expertise to create and implement safeguards which anticipate dangerous consequences of failures, monitor failures and their consequences, lessen the likelihood of failures that might cause harm and take appropriate remedial actions. Buyer will fully indemnify TI and its representatives against any damages arising out of the use of any TI components in safety-critical applications.

In some cases, TI components may be promoted specifically to facilitate safety-related applications. With such components, TI's goal is to help enable customers to design and create their own end-product solutions that meet applicable functional safety standards and requirements. Nonetheless, such components are subject to these terms.

No TI components are authorized for use in FDA Class III (or similar life-critical medical equipment) unless authorized officers of the parties have executed a special agreement specifically governing such use.

Only those TI components which TI has specifically designated as military grade or "enhanced plastic" are designed and intended for use in military/aerospace applications or environments. Buyer acknowledges and agrees that any military or aerospace use of TI components which have **not** been so designated is solely at the Buyer's risk, and that Buyer is solely responsible for compliance with all legal and regulatory requirements in connection with such use.

TI has specifically designated certain components as meeting ISO/TS16949 requirements, mainly for automotive use. In any case of use of non-designated products, TI will not be responsible for any failure to meet ISO/TS16949.
