

OPA656 Wideband, Unity-Gain Stable, FET-Input Operational Amplifier

1 Features

- 500 MHz Unity-gain Bandwidth
- Low Input Bias Current: 2 pA
- Low Offset And Drift: $\pm 250 \mu\text{V}$, $\pm 2 \mu\text{V}/^\circ\text{C}$
- Low Distortion: 74-dB SFDR at 5 MHz
- High-Output Current: 70 mA
- Low Input Voltage Noise: $7 \text{ nV}/\sqrt{\text{Hz}}$

2 Applications

- Wideband Photodiode Amplifiers
- Sample-and-Hold Buffers
- CCD Output Buffers
- ADC Input Buffers
- Wideband Precision Amplifiers
- Test and Measurement Front Ends

3 Description

The OPA656 device combines a very wideband, unity-gain stable, voltage-feedback operational amplifier with a FET-input stage to offer an ultra high dynamic-range amplifier for Analog-to-Digital Converter (ADC) buffering and transimpedance applications. Extremely low DC errors give good precision in optical applications.

The high unity-gain stable bandwidth and JFET input allows exceptional performance in high-speed, low-noise integrators.

The high input impedance and low bias current provided by the FET input is supported by the ultra-low $7\text{-nV}/\sqrt{\text{Hz}}$ input voltage noise to achieve a very low integrated noise in wideband photodiode transimpedance applications.

Broad transimpedance bandwidths are achievable given the OPA656 device's high 230-MHz gain bandwidth product. As shown below, a -3-dB bandwidth of 1 MHz is provided even for a high $1\text{-M}\Omega$ transimpedance gain from a 47-pF source capacitance.

Device Information⁽¹⁾

PART NUMBER	PACKAGE	BODY SIZE (NOM)
OPA656	SOIC (8)	2.90 mm x 1.60 mm
	SOT-23 (5)	4.90 mm x 3.91 mm

(1) For all available packages, see the orderable addendum at the end of the data sheet.

7 Specifications

7.1 Absolute Maximum Ratings

over operating free-air temperature range (unless otherwise noted) ⁽¹⁾

	MIN	MAX	UNIT
Supply voltage (Total Bipolar Supplies)		±6.5	V
Internal power dissipation	See Thermal Information		
Differential input voltage	-V _S	+V _S	
Input voltage	-V _S	+V _S	
Junction temperature, T _J		150	°C
Storage temperature, T _{stg}	-65	125	°C

(1) Stresses beyond those listed under *Absolute Maximum Ratings* may cause permanent damage to the device. These are stress ratings only, which do not imply functional operation of the device at these or any other conditions beyond those indicated under *Recommended Operating Conditions*. Exposure to absolute-maximum-rated conditions for extended periods may affect device reliability.

7.2 ESD Ratings

		VALUE	UNIT
V _(ESD)	Electrostatic discharge	Human-body model (HBM), per ANSI/ESDA/JEDEC JS-001 ⁽¹⁾	V
		Charged-device model (CDM), per JEDEC specification JESD22-C101 ⁽²⁾	
		Machine Model	

(1) JEDEC document JEP155 states that 500-V HBM allows safe manufacturing with a standard ESD control process.

(2) JEDEC document JEP157 states that 250-V CDM allows safe manufacturing with a standard ESD control process.

7.3 Recommended Operating Conditions

over operating free-air temperature range (unless otherwise noted)

(1) Test Levels: (A) 100% tested at 25°C. Over temperature limits by characterization and simulation. (B) Limits set by characterization and simulation. (C) Typical value only for information.

(2) Junction temperature = ambient for 25°C min/max specifications.

(3) Current is considered positive out-of-node. V_{CM} is the input common-mode voltage.

(4) Junction temperature = ambient at low temperature limit; junction temperature = ambient +20°C at high temperature limit for over temperature minimum and maximum specifications.

Electrical Characteristics (continued)

R_F = 250 Ω, R_L = 100 Ω, and G = 2 V/V, unless otherwise noted. See [Figure 1](#) for AC performance.

8 Detailed Description

8.1 Overview

The OPA656 is high gain-bandwidth, voltage feedback operational amplifier featuring a low noise JFET input stage. The OPA656 is compensated to be unity gain stable. The OPA656 finds wide use in optical front-end applications and in test and measurement systems that require high input impedance.

8.2 Feature Description

8.2.1 Input and ESD Protection

The OPA656 is built using a very high speed complementary bipolar process. The internal junction breakdown voltages are relatively low for these very small geometry devices. These breakdowns are reflected in the [Absolute Maximum Ratings](#) table. All device pins are protected with internal ESD protection diodes to the power supplies as shown in [Figure 28](#).

These diodes provide moderate protection to input overdrive voltages above the supplies as well. The protection diodes can typically support 30-mA continuous current. Where higher currents are possible (for example, in systems with $\pm 12\text{-V}$ supply parts driving into the OPA656), current limiting series resistors should be added into the two inputs. Keep these resistor values as low as possible because high values degrade both noise performance and frequency response.

Figure 28. Internal ESD Protection

8.3 Device Functional Modes

8.3.1 Split-Supply Operation ($\pm 4\text{ V}$ to $\pm 6\text{ V}$)

To facilitate testing with common lab equipment, the OPA656 may be configured to allow for split-supply operation. This configuration eases lab testing because the mid-point between the power rails is ground, and most signal generators, network analyzers, oscilloscopes, spectrum analyzers and other lab equipment reference their inputs and outputs to ground. [Figure 29](#) and [Figure 30](#) show the OPA656 configured in a simple noninverting and inverting configuration respectively with $\pm 5\text{-V}$ supplies. The input and output will swing symmetrically around ground. Due to its ease of use, split-supply operation is preferred in systems where signals swing around ground, but it requires generation of two supply rails.

8.3.2 Single-Supply Operation (8 V to 12 V)

Many newer systems use single power supply to improve efficiency and reduce the cost of the extra power supply. The OPA656 is designed for use with split-supply configuration; however, it can be used with a single-supply with no change in performance, as long as the input and output are biased within the linear operation of the device. To change the circuit from split supply to single supply, level shift all the voltages by 1/2 the difference between the power supply rails. An additional advantage of configuring an amplifier for single-supply operation is that the effects of $-PSRR$ will be minimized because the low supply rail has been grounded.

9 Application and Implementation

NOTE

Information in the following applications sections is not part of the TI component specification, and TI does not warrant its accuracy or completeness. TI's customers are responsible for determining suitability of components for their purposes. Customers should validate and test their design implementation to confirm system functionality.

9.1 Application Information

9.1.1 Wideband, Noninverting Operation

The OPA656 provides a unique combination of a broadband, unity gain stable, voltage-feedback amplifier with the DC precision of a trimmed JFET-input stage. Its very high Gain Bandwidth Product (GBP) of 230 MHz can be used to either deliver high signal bandwidths for low-gain buffers, or to deliver broadband, low-noise transimpedance bandwidth to photodiode-detector applications. To achieve the full performance of the OPA656, careful attention to printed-circuit-board (PCB) layout and component selection is required as discussed in the remaining sections of this data sheet.

Figure 29 shows the noninverting gain of +2 V/V circuit used as the basis for most of the Typical Characteristics. Most of the curves were characterized using signal sources with 50-Ω driving impedance, and with measurement equipment presenting a 50-Ω load impedance. In Figure 29, the 50-Ω shunt resistor at the V_I terminal matches the source impedance of the test generator, while the 50-Ω series resistor at the V_O terminal provides a matching resistor for the measurement equipment load. Generally, data sheet voltage swing specifications are at the output pin (V_O in Figure 29) while output power specifications are at the matched 50-Ω load. The total 100-Ω load at the output combined with the 500-Ω total feedback network load, presents the OPA656 with an effective output load of 83 Ω for the circuit of Figure 29.

Figure 29. Noninverting $G = +2$ V/V Specifications and Test Circuit

Voltage-feedback operational amplifiers, unlike current feedback products, can use a wide range of resistor values to set their gain. To retain a controlled frequency response for the noninverting voltage amplifier of Figure 29, the parallel combination of $R_F \parallel R_G$ should always $< 200 \Omega$. In the noninverting configuration, the parallel combination of $R_F \parallel R_G$ will form a pole with the parasitic input capacitance at the inverting node of the OPA656 (including layout parasitics). For best performance, this pole should be at a frequency greater than the closed loop bandwidth for the OPA656. For this reason, TI recommends a direct short from output to inverting input for the unity gain follower application.

Application Information (continued)

9.1.2 Wideband, Inverting Gain Operation

The circuit of [Figure 30](#) shows the inverting gain of -1 V/V test circuit used for most of the inverting Typical Characteristics. In this case, an additional resistor R_M is used to achieve the $50\text{-}\Omega$ input impedance required by the test equipment using in characterization. This input impedance matching is optional in a circuit board environment where the OPA656 is used as an inverting amplifier at the output of a prior stage.

In this configuration, the output sees the feedback resistor as an additional load in parallel with the $100\text{-}\Omega$ load used for test. It is often useful to increase the R_F value to decrease the loading on the output (improving harmonic distortion) with the constraint that the parallel combination of $R_F \parallel R_G < 200\ \Omega$. For higher inverting gains with the DC precision provided by the FET input OPA656, consider the higher gain bandwidth product [OPA657](#).

Figure 30. Inverting $G = -1$ V/V Specifications and Test Circuit

[Figure 30](#) also shows the noninverting input tied directly to ground. Often, a bias current canceling resistor to ground is included here to null out the DC errors caused by input bias current effects. This is only useful when the input bias currents are matched. For a JFET part like the OPA656, the input bias currents do not match but are so low to begin with (< 5 pA) that DC errors due to input bias currents are negligible. Hence, no resistor is recommended at the noninverting inputs for the inverting signal path condition.

9.1.3 Operating Suggestions

9.1.3.1 Setting Resistor Values to Minimize Noise

The OPA656 provides a very low input noise voltage while requiring a low 14-mA quiescent supply current. To take full advantage of this low input noise, careful attention to the other possible noise contributors is required. [Figure 31](#) shows the operational amplifier noise analysis model with all the noise terms included. In this model, all the noise terms are taken to be noise voltage or current density terms in either $\text{nV}/\sqrt{\text{Hz}}$ or $\text{pA}/\sqrt{\text{Hz}}$.

Application Information (continued)

Figure 31. Operational Amplifier Noise Analysis Model

The total output spot noise voltage can be computed as the square root of the squared contributing terms to the output noise voltage. This computation is adding all the contributing noise powers at the output by superposition, then taking the square root to get back to a spot noise voltage. Equation 1 shows the general form for this output noise voltage using the terms shown in Figure 31.

$$E_O = \sqrt{\left(E_{NI}^2 + (I_{BN}R_S)^2 + 4kTR_S\right)NG^2 + \left(I_{BI}R_F\right)^2 + 4kTR_FNG} \tag{1}$$

Dividing this expression by the noise gain ($GN = 1 + R_F/R_G$) will give the equivalent input referred spot noise voltage at the noninverting input as shown in Equation 2.

$$E_N = \sqrt{E_{NI}^2 + (I_{BN}R_S)^2 + 4kTR_S + \left(\frac{I_{BI}R_F}{NG}\right)^2 + \frac{4kTR_F}{NG}} \tag{2}$$

Putting high resistor values into Equation 2 can quickly dominate the total equivalent input referred noise. A source impedance on the noninverting input of 3 kΩ will add a Johnson voltage noise term equal to just that for the amplifier itself (7 nV/√Hz). While the JFET input of the OPA656 is ideal for high source impedance applications, both the overall bandwidth and noise will be limited by higher source impedances in the noninverting configuration of Figure 29.

9.1.3.2 Frequency Response Control

Voltage-feedback op amps like the OPA656 exhibit decreasing signal bandwidth as the signal gain is increased. In theory, this relationship is described by the GBP shown in the *Electrical Characteristics*. Ideally, dividing GBP by the noninverting signal gain (also called the Noise Gain, or NG) will predict the closed-loop bandwidth. In practice, this only holds true when the phase margin approaches 90°, as it does in high-gain configurations. At low gains (increased feedback factors), most high-speed amplifiers will exhibit a more complex response with lower phase margin. The OPA656 is compensated to give a maximally flat 2nd-order Butterworth closed loop response at a noninverting gain of +2 V/V (Figure 29). This results in a typical gain of +2 V/V bandwidth of 200 MHz, far exceeding that predicted by dividing the 230-MHz GBP by 2. Increasing the gain will cause the phase margin to approach 90° and the bandwidth to more closely approach the predicted value of (GBP/NG). At a gain of +10 V/V the OPA656 will show the 23-MHz bandwidth predicted using the simple formula and the typical GBP of 230 MHz.

Unity-gain stable operational amplifiers like the OPA656 can also be bandlimited using a capacitor across the feedback resistor. For the noninverting configuration of Figure 29, a capacitor across the feedback resistor will decrease the gain with frequency down to a gain of +1 V/V. For instance, to bandlimit the gain of +2 V/V design to 20 MHz, a 32-pF capacitor can be placed in parallel with the 250-Ω feedback resistor. This will, however, only decrease the gain from +2 V/V to +1 V/V. Using a feedback capacitor to limit the signal bandwidth is more effective in the inverting configuration of Figure 30. Adding that same capacitor to the feedback of Figure 30 will set a pole in the signal frequency response at 20 MHz, but in this case it will continue to attenuate the signal gain to below 1. However, the output noise contribution due the input voltage noise of the OPA656 will still only be reduced to a gain of +1 V/V with the addition of the feedback capacitor.

Application Information (continued)

9.1.3.3 Driving Capacitive Loads

One of the most demanding and yet very common load conditions for an operational amplifier is capacitive loading. Often, the capacitive load is the input of an ADC—including additional external capacitance which may be recommended to improve ADC linearity. A high-speed, high open-loop gain amplifier like the OPA656 can be very susceptible to decreased stability and closed-loop response peaking when a capacitive load is placed directly on the output pin. When the amplifier's open loop output resistance is considered, this capacitive load introduces an additional pole in the signal path that can decrease the phase margin. Several external solutions to this problem have been suggested. When the primary considerations are frequency response flatness, pulse response fidelity and/or distortion, the simplest and most effective solution is to isolate the capacitive load from the feedback loop by inserting a series isolation resistor between the amplifier output and the capacitive load. This does not eliminate the pole from the loop response, but rather shifts it and adds a zero at a higher frequency. The additional zero acts to cancel the phase lag from the capacitive load pole, thus increasing the phase margin and improving stability.

The *Typical Characteristics: $V_S = \pm 5\text{ V}$* show the recommended R_S versus Capacitive Load and the resulting frequency response at the load. In this case, a design target of a maximally flat frequency response was used. Lower values of R_S may be used if some peaking can be tolerated. Also, operating at higher gains (than the +2 used in *Typical Characteristics: $V_S = \pm 5\text{ V}$*) will require lower values of R_S for a minimally peaked frequency response. Parasitic capacitive loads greater than 2 pF can begin to degrade the performance of the OPA656. Long PC board traces, unmatched cables, and connections to multiple devices can easily cause this value to be exceeded. Always consider this effect carefully, and add the recommended series resistor as close as possible to the OPA656 output pin (see [Layout](#) section).

9.1.3.4 Distortion Performance

The OPA656 is capable of delivering a low distortion signal at high frequencies over a wide range of gains. The distortion plots in the *Typical Characteristics: $V_S = \pm 5\text{ V}$* show the typical distortion under a wide variety of conditions.

Generally, until the fundamental signal reaches very high frequencies or powers, the 2nd-harmonic will dominate the distortion with negligible 3rd-harmonic component. Focusing then on the 2nd-harmonic, increasing the load impedance improves distortion directly. Remember that the total load includes the feedback network—in the noninverting configuration this is sum of $R_F + R_G$, while in the inverting configuration this is just R_F (see [Figure 29](#)). Increasing output voltage swing increases harmonic distortion directly. A 6-dB increase in output swing will generally increase the 2nd-harmonic 12 dB and the 3rd-harmonic 18 dB. Increasing the signal gain will also increase the 2nd-harmonic distortion. Again a 6-dB increase in gain will increase the 2nd- and 3rd-harmonic by about 6 dB even with a constant output power and frequency. And finally, the distortion increases as the fundamental frequency increases due to the rolloff in the loop gain with frequency. Conversely, the distortion will improve going to lower frequencies down to the dominant open loop pole at approximately 100 kHz. Starting from the -70 dBc 2nd-harmonic for a 5 MHz, 2V_{PP} fundamental into a 200-Ω load at $G = +2\text{ V/V}$ (from the *Typical Characteristics: $V_S = \pm 5\text{ V}$*), the 2nd-harmonic distortion for frequencies lower than 100 kHz will be < -105 dBc.

The OPA656 has an extremely low 3rd-order harmonic distortion. This also shows up in the 2-tone 3rd-order intermodulation spurious (IM3) response curves. The 3rd-order spurious levels are extremely low < -80 dBc) at low output power levels. The output stage continues to hold them low even as the fundamental power reaches higher levels. As the *Typical Characteristics: $V_S = \pm 5\text{ V}$* show, the spurious intermodulation powers do not increase as predicted by a traditional intercept model. As the fundamental power level increases, the dynamic range does not decrease significantly. For 2 tones centered at 10 MHz, with 4 dBm/tone into a matched 50-Ω load (that is, 1V_{PP} for each tone at the load, which requires 4 VPP for the overall 2-tone envelope at the output pin), the *Typical Characteristics: $V_S = \pm 5\text{ V}$* show a 78-dBc difference between the test tone and the 3rd-order intermodulation spurious levels. This exceptional performance improves further when operating at lower frequencies and/or higher load impedances.

Application Information (continued)

9.1.3.5 DC Accuracy and Offset Control

The OPA656 can provide excellent DC accuracy due to its high open-loop gain, high common-mode rejection, high power-supply rejection, and its trimmed input offset voltage (and drift) along with the negligible errors introduced by the low input bias current. For the best DC precision, a highgrade version (OPA656UB or OPA656NB) screens the key DC parameters to an even tighter limits. Both standard- and high-grade versions take advantage of a new final test technique to 100% test input offset voltage drift over temperature. This discussion will use the high-grade typical and minimum and maximum electrical characteristics for illustration; however, an identical analysis applies to the standard-grade version.

The total output DC offset voltage in any configuration and temperature will be the combination of a number of possible error terms. In a JFET part like the OPA656, the input bias current terms are typically quite low but are unmatched. Using bias current cancellation techniques, more typical in bipolar input amplifiers, does not improve output DC offset errors. Errors due to the input bias current will only become dominant at elevated temperatures. The OPA656 shows the typical 2x increase in every 10°C common to JFET-input stage amplifiers. Using the 5-pA maximum tested value at 25°C, and a 20°C internal self heating (see [Thermal Considerations](#)), the maximum input bias current at 85°C ambient will be $5 \text{ pA} \times 2^{(105 - 25)/10} = 1280 \text{ pA}$. For noninverting configurations, this term only begins to be a significant term versus the input offset voltage for source impedances > 750 kΩ. This would also be the feedback-resistor value for transimpedance applications (see [Figure 32](#)) where the output DC error due to inverting input bias current is on the order of that contributed by the input offset voltage. In general, except for these extremely high impedance values, the output DC errors due to the input bias current may be neglected.

After the input offset voltage itself, the most significant term contributing to output offset voltage is the PSRR for the negative supply. This term is modeled as an input offset voltage shift due to changes in the negative power-supply voltage (and similarly for the +PSRR). The high-grade test limit for –PSRR is 62 dB. This translates into 1.59-mV/V input offset voltage shift = $10^{(-62/20)}$. In the worst case, a $\pm 0.38 \text{ V}$ ($\pm 7.6\%$) shift in the negative supply voltage will produce a $\pm 0.6 \text{ mV}$ apparent input offset voltage shift. Because this is comparable to the tested limit of $\pm 0.6 \text{ mV}$ input offset voltage, a careful control of the negative supply voltage is required. The +PSRR is tested to a minimum value of 74 dB. This translates into $10^{(-74/20)} = 0.2 \text{ mV/V}$ sensitivity for the input offset voltage to positive power supply changes.

As an example, compute the worst-case output DC error for the transimpedance circuit of [Figure 32](#) at 25°C and then the shift over the 0°C to 70°C range given the following assumptions.

Negative Power Supply = –5 V $\pm 0.2\text{V}$ with a $\pm 5\text{mV}/^\circ\text{C}$ worst-case shift

Positive Power Supply = +5 V $\pm 0.2\text{V}$ with a $\pm 5\text{mV}/^\circ\text{C}$ worst-case shift

Initial 25°C Output DC Error Band

= $\pm 0.3 \text{ mV}$ (due to the –PSRR = $1.59 \text{ mV/V} \times \pm 0.2 \text{ V}$)

$\pm 0.04 \text{ mV}$ (due to the +PSRR = $0.2 \text{ mV/V} \times \pm 0.2 \text{ V}$)

$\pm 0.6 \text{ mV}$ Input Offset Voltage

Total = $\pm 0.94 \text{ mV}$

This would be the worst-case error band in volume production at 25°C acceptance testing given the conditions stated.

Over the temperature range of 0°C to 70°C, we can expect the following worst-case shifting from initial value. A 20°C internal junction self heating is assumed here.

$\pm 0.36 \text{ mV}$ (OPA656 high-grade input offset drift) = $\pm 6 \text{ } \mu\text{V}/^\circ\text{C} \times (70^\circ\text{C} + 20^\circ\text{C} - 25^\circ\text{C})$

$\pm 0.23 \text{ mV}$ (–PSRR of 60 dB with $5 \text{ mV} \times (70^\circ\text{C} - 25^\circ\text{C})$ supply shift)

$\pm 0.06 \text{ mV}$ (+PSRR of 72 dB with $5 \text{ mV} \times (70^\circ\text{C} - 25^\circ\text{C})$ supply shift)

Total = $\pm 0.65 \text{ mV}$

This would be the worst-case shift from initial offset over a 0°C to 70°C ambient for the conditions stated. Typical initial output DC error bands and shifts over temperature will be much lower than these worst-case estimates.

Application Information (continued)

In the transimpedance configuration, the CMRR errors can be neglected because the input common mode voltage is held at ground. For noninverting gain configurations (see Figure 29), the CMRR term must be considered but will typically be far lower than the input offset voltage term. With a tested minimum of 80 dB (100 $\mu\text{V/V}$), the added apparent DC error will be no more than ± 0.2 mV for a ± 2 -V input swing to the circuit of Figure 29.

9.2 Typical Application

The high GBP and low input voltage and current noise for the OPA656 make it an ideal wideband transimpedance amplifier for moderate to high transimpedance gains.

Figure 32. Wideband, High-Sensitivity, Transimpedance Amplifier

9.2.1 Design Requirements

Design a high-bandwidth, high-gain transimpedance amplifier with the design requirements shown in Table 1.

Table 1. Design Requirements

TARGET BANDWIDTH (MHz)	TRANSIMPEDANCE GAIN (KΩ)	PHOTODIODE CAPACITANCE (pF)
4	100	21

9.2.2 Detailed Design Procedure

Designs that require high bandwidth from a large area detector with relatively high transimpedance gain benefit from the low input voltage noise of the OPA656. This input voltage noise is peaked up over frequency by the diode source capacitance, and can, in many cases, become the limiting factor to input sensitivity. The key elements to the design are the expected diode capacitance (C_D) with the reverse bias voltage (V_B) applied the desired transimpedance gain, R_F , and the GBP for the OPA656 (230 MHz). Figure 32 shows a transimpedance circuit with the parameters as described in Table 1. With these three variables set (and including the parasitic input capacitance for the OPA656 and the PCB added to C_D), the feedback capacitor value (C_F) may be set to control the frequency response. To achieve a maximally-flat second-order Butterworth frequency response, the feedback pole should be set to:

$$\frac{1}{2\pi R_F C_F} = \sqrt{\frac{\text{GBP}}{4\pi R_F C_D}} \quad (3)$$

The input capacitance of the amplifier is the sum of its common-mode and differential capacitance (0.7+2.8) pF. The parasitic capacitance from the photo-diode package and the PCB is approximately 0.3 pF. This results in a total input capacitance, C_D {D should be a subscript} = 24.8 pF. From Equation 3, the feedback pole should be set at 2.7 MHz. Setting the pole at 2.7 MHz requires a total feedback capacitance of 0.585 pF

The approximate -3 -dB bandwidth of the transimpedance amplifier circuit is given by:

$$f_{-3dB} = \sqrt{GBP / (2\pi R_F C_D)} \text{ Hz} \tag{4}$$

Equation 4 estimates a closed-loop bandwidth of 3.84 MHz. The total feedback capacitance for the circuit used in the measurement is estimated to be 0.520 pF. The total feedback capacitance includes the physical 0.4-pF feedback capacitor in parallel with 120-fF of parasitic capacitance due to the feedback resistor and PCB trace. The parasitic capacitance from the PCB trace can be minimized by removing the ground and power planes in the feedback path. A TINA SPICE simulation of the circuit in Figure 32 resulted in a closed-loop bandwidth of 4.2 MHz.

Figure 33 shows the measured output noise of the system. The low-frequency output noise of 45 nV/√Hz gets input-referred to 0.45 pA/√Hz. The transimpedance gain resistor is the dominant noise source with the operational amplifier itself contributing a negligible amount, reflecting one of the main benefits in using a JFET input amplifier in a high-gain transimpedance application. If the total output noise of the TIA is bandlimited to a frequency less than the feedback pole frequency, a very simple expression for the equivalent output noise voltage can be derived as shown in Equation 5.

$$V_{OUTN} = \sqrt{(I_N R_F)^2 + 4kTR_F + E_N^2 + \frac{(E_N 2\pi C_D R_F F)^2}{3}}$$

where

- V_{OUTN} = Equivalent output noise when band limited to $F < 1 / (2 \Omega RfCf)$
 - I_N = Input current noise for the operational amplifier inverting input
 - E_N = Input voltage noise for the operational amplifier
 - C_D = Diode capacitance including operational amplifier and PCB parasitic capacitance
 - F = Band-limiting frequency in Hz (usually a postfilter before further signal processing)
 - $4 kT = 1.6 \text{ e} - 20 \text{ J}$ at $T = 290^\circ\text{K}$
- (5)

Figure 34 shows the measured pulse response to a 2-μA input current pulse. The output voltage measured on the scope is 0.1 V because of the 50-Ω termination to the scope. The measured rise/fall time and overshoot match very well with simulation. Based on the measured rise and fall time of 85 ns, the approximate bandwidth of the circuit = 0.35/85 ns = 4.1 MHz, which also matches the theoretical value calculated using Equation 4.

9.2.3 Application Curves

10 Power Supply Recommendations

The OPA656 is intended for operation on ± 5 -V supplies. Single-supply operation is allowed with minimal change from the stated specifications and performance from a single supply of 8 V to 12 V maximum. The limit to lower supply voltage operation is the useable input voltage range for the JFET-input stage. Operating from a single supply of 12 V can have numerous advantages. With the negative supply at ground, the DC errors due to the $-PSRR$ term can be minimized. Typically, AC performance improves slightly at 12-V operation with minimal increase in supply current.

11 Layout

11.1 Layout Guidelines

Achieving optimum performance with a high-frequency amplifier like the OPA656 requires careful attention to board layout parasitics and external component types. Recommendations that will optimize performance include.

1. **Minimize parasitic capacitance** to any AC ground for all of the signal I/O pins. Parasitic capacitance on the output and inverting input pins can cause instability—on the noninverting input, it can react with the source impedance to cause unintentional bandlimiting. To reduce unwanted capacitance, a window around the signal I/O pins should be opened in all of the ground and power planes around those pins. Otherwise, ground and power planes should be unbroken elsewhere on the board.
2. **Minimize the distance** ($< 0.25"$) from the power-supply pins to high-frequency 0.1- μF decoupling capacitors. At the device pins, the ground and power plane layout should not be in close proximity to the signal I/O pins. Avoid narrow power and ground traces to minimize inductance between the pins and the decoupling capacitors. The power-supply connections should always be decoupled with these capacitors. Larger (2.2- μF to 6.8- μF) decoupling capacitors, effective at lower frequency, should also be used on the supply pins. These may be placed somewhat farther from the device and may be shared among several devices in the same area of the PC board.
3. **Careful selection and placement of external components will preserve the high frequency performance of the OPA656.** Resistors should be a very low reactance type. Surface-mount resistors work best and allow a tighter overall layout. Metal film and carbon composition axially leaded resistors can also provide good high frequency performance. Again, keep their leads and PCB trace length as short as possible. Never use wirewound type resistors in a high frequency application. Because the output pin and inverting input pin are the most sensitive to parasitic capacitance, always position the feedback and series output resistor, if any, as close as possible to the output pin. Other network components, such as noninverting input termination resistors, should also be placed close to the package. Where double side component mounting is allowed, place the feedback resistor directly under the package on the other side of the board between the output and inverting input pins. Even with a low parasitic capacitance shunting the external resistors, excessively high resistor values can create significant time constants that can degrade performance. Good axial metal film or surface mount resistors have approximately 0.2 pF in shunt with the resistor. For resistor values $> 1.5 \text{ k}\Omega$, this parasitic capacitance can add a pole and/or zero below 500 MHz that can affect circuit operation. Keep resistor values as low as possible consistent with load driving considerations. It has been suggested here that a good starting point for design would be to keep $R_F \parallel R_G < 250 \Omega$ for voltage amplifier applications. Doing this will automatically keep the resistor noise terms low, and minimize the effect of their parasitic capacitance. Transimpedance applications (see) can use whatever feedback resistor is required by the application as long as the feedback compensation capacitor is set considering all parasitic capacitance terms on the inverting node.
4. **Connections to other wideband devices** on the board may be made with short direct traces or through onboard transmission lines. For short connections, consider the trace and the input to the next device as a lumped capacitive load. Relatively wide traces (50 mils to 100 mils) should be used, preferably with ground and power planes opened up around them. Estimate the total capacitive load and set R_S from the plot of *Recommended R_S vs Capacitive Load*. Low parasitic capacitive loads ($< 5 \text{ pF}$) may not need an R_S because the OPA656 is nominally compensated to operate with a 2-pF parasitic load. Higher parasitic capacitive loads without an R_S are allowed as the signal gain increases (increasing the unloaded phase margin) If a long trace is required, and the 6-dB signal loss intrinsic to a doubly-terminated transmission line is acceptable, implement a matched impedance transmission line using microstrip or stripline techniques (consult an ECL design handbook for microstrip and stripline layout techniques). A 50- Ω environment is normally not necessary onboard, and in fact a higher impedance environment will improve distortion as shown in the distortion versus load plots. With a characteristic board trace impedance defined based on board material and trace dimensions, a matching series resistor into the trace from the output of the OPA656 is used as well as a terminating shunt resistor at the input of the destination device. Remember also that the terminating impedance will be the parallel combination of the shunt resistor and the input impedance of the destination device— this total effective impedance should be set to match the trace impedance. If the 6-dB attenuation of a doubly-terminated transmission line is unacceptable, a long trace can be series-terminated at the source end only. Treat the trace as a capacitive load in this case and set the series resistor value as shown in the plot of *Recommended R_S vs Capacitive Load*. This will not preserve signal integrity as well as a doubly-terminated line. If the input impedance of the destination device is low, there will be some signal attenuation due to the voltage divider formed by the series output into the terminating impedance.

Layout Guidelines (continued)

5. **Socketing a high speed part like the OPA656 is not recommended.** The additional lead length and pin-to-pin capacitance introduced by the socket can create an extremely troublesome parasitic network which can make it almost impossible to achieve a smooth, stable frequency response. Best results are obtained by soldering the OPA656 onto the board.

11.1.1 Demonstration Fixtures

Two printed-circuit-boards (PCBs) are available to assist in the initial evaluation of circuit performance using the OPA656 device in its two package options. Both of these are offered free of charge as unpopulated PCBs, delivered with a user's guide. The summary information for these fixtures is shown in Table 2.

Table 2. Demonstration Fixtures by Package

PRODUCT	PACKAGE	ORDERING NUMBER	LITERATURE NUMBER
OPA656U	SO-8	DEM-OPA-SO-1A	SBOU009
OPA656N	SOT23-5	DEM-OPA-SOT-1A	SBOU010

The demonstration fixtures can be requested at the Texas Instruments website (www.ti.com) through the OPA656 product folder.

11.2 Layout Example

Figure 35. Layout Recommendation

11.3 Thermal Considerations

The OPA656 will not require heatsinking or airflow in most applications. Maximum allowed junction temperature will set the maximum allowed internal power dissipation as described below. In no case should the maximum junction temperature be allowed to exceed 150°C.

Operating junction temperature (T_J) is given by $T_A + P_D \times \theta_{JA}$. The total internal power dissipation (P_D) is the sum of quiescent power (P_{DQ}) and additional power dissipated in the output stage (P_{DL}) to deliver load power. Quiescent power is simply the specified no-load supply current times the total supply voltage across the part. P_{DL} will depend on the required output signal and load but would, for a grounded resistive load, be at a maximum when the output is fixed at a voltage equal to 1/2 of either supply voltage (for equal bipolar supplies). Under this condition $P_{DL} = V_S^2 / (4 \times R_L)$ where R_L includes feedback network loading.

Note that it is the power in the output stage and not into the load that determines internal power dissipation.

As a worst-case example, compute the maximum T_J using an OPA656N (SOT23-5 package) in the circuit of [Figure 29](#) operating at the maximum specified ambient temperature of +85°C and driving a grounded 100-Ω load.

$$P_D = 10 \text{ V} \times 16.1 \text{ mA} + 5^2 / (4 \times (100 \text{ } \Omega \parallel 800 \text{ } \Omega)) = 231 \text{ mW}$$

$$\text{Maximum } T_J = 85^\circ\text{C} + (0.23 \text{ W} \times 150^\circ\text{C/W}) = 120^\circ\text{C}.$$

All actual applications will be operating at lower internal power and junction temperature.

12 Device and Documentation Support

12.1 Community Resources

The following links connect to TI community resources. Linked contents are provided "AS IS" by the respective contributors. They do not constitute TI specifications and do not necessarily reflect TI's views; see TI's [Terms of Use](#).

TI E2E™ Online Community *TI's Engineer-to-Engineer (E2E) Community*. Created to foster collaboration among engineers. At e2e.ti.com, you can ask questions, share knowledge, explore ideas and help solve problems with fellow engineers.

Design Support *TI's Design Support* Quickly find helpful E2E forums along with design support tools and contact information for technical support.

12.2 Trademarks

E2E is a trademark of Texas Instruments.
All other trademarks are the property of their respective owners.

12.3 Electrostatic Discharge Caution

These devices have limited built-in ESD protection. The leads should be shorted together or the device placed in conductive foam during storage or handling to prevent electrostatic damage to the MOS gates.

12.4 Glossary

[SLYZ022](#) — *TI Glossary*.

This glossary lists and explains terms, acronyms, and definitions.

13 Mechanical, Packaging, and Orderable Information

The following pages include mechanical, packaging, and orderable information. This information is the most current data available for the designated devices. This data is subject to change without notice and revision of this document. For browser-based versions of this data sheet, refer to the left-hand navigation.

PACKAGING INFORMATION

Orderable Device	Status (1)	Package Type	Package Drawing	Pins	Package Qty	Eco Plan (2)	Lead/Ball Finish (6)	MSL Peak Temp (3)	Op Temp (°C)	Device Marking (4/5)	Samples
OPA656N/250	ACTIVE	SOT-23	DBV	5	250	Green (RoHS & no Sb/Br)	CU NIPDAU	Level-2-260C-1 YEAR	-40 to 85	B56	Samples

(1) The marketing status values are defined as follows:

ACTIVE: Product device recommended for new designs.

LIFEBUY: TI has announced that the device will be discontinued, and a lifetime-buy period is in effect.

NRND: Not recommended for new designs. Device is in production to support existing customers, but TI does not recommend using this part in a new design.

PREVIEW: Device has been announced but is not in production. Samples may or may not be available.

OBSELETE: TI has discontinued the production of the device.

(2) Eco Plan - The planned eco-friendly classification: Pb-Free (RoHS), Pb-Free (RoHS Exempt), or Green (RoHS & no Sb/Br) - please check <http://www.ti.com/productcontent> for the latest availability information and additional product content details.

TBD: The Pb-Free/Green conversion plan has not been defined.

Pb-Free (RoHS): TI's terms "Lead-Free" or "Pb-Free" mean semiconductor products that are compatible with the current RoHS requirements for all 6 substances, including the requirement that lead not exceed 0.1% by weight in homogeneous materials. Where designed to be soldered at high temperatures, TI Pb-Free products are suitable for use in specified lead-free processes.

Pb-Free (RoHS Exempt): This component has a RoHS exemption for either 1) lead-based flip-chip solder bumps used between the die and package, or 2) lead-based die adhesive used between the die and leadframe. The component is otherwise considered Pb-Free (RoHS compatible) as defined above.

Green (RoHS & no Sb/Br): TI defines "Green" to mean Pb-Free (RoHS compatible), and free of Bromine (Br) and Antimony (Sb) based flame retardants (Br or Sb do not exceed 0.1% by weight in homogeneous material)

⁽³⁾ MSL, Peak Temp. - The Moisture Sensitivity Level rating according to the JEDEC industry standard classifications, and peak solder temperature.

⁽⁴⁾ There may be additional marking, which relates to the logo, the lot trace code information, or the environmental category on the device.

⁽⁵⁾ Multiple Device Markings will be inside parentheses. Only one Device Marking contained in parentheses and separated by a "~" will appear on a device. If a line is indented then it is a continuation of the previous line and the two combined represent the entire Device Marking for that device.

⁽⁶⁾ Lead/Ball Finish - Orderable Devices may have multiple material finish options. Finish options are separated by a vertical ruled line. Lead/Ball Finish values may wrap to two lines if the finish value exceeds the maximum column width.

Important Information and Disclaimer:The information provided on this page represents TI's knowledge and belief as of the date that it is provided. TI bases its knowledge and belief on information provided by third parties, and makes no representation or warranty as to the accuracy of such information. Efforts are underway to better integrate information from third parties. TI has taken and continues to take reasonable steps to provide representative and accurate information but may not have conducted destructive testing or chemical analysis on incoming materials and chemicals. TI and TI suppliers consider certain information to be proprietary, and thus CAS numbers and other limited information may not be available for release.

In no event shall TI's liability arising out of such information exceed the total purchase price of the TI part(s) at issue in this document sold by TI to Customer on an annual basis.

TAPE AND REEL INFORMATION

QUADRANT ASSIGNMENTS FOR PIN 1 ORIENTATION IN TAPE

*All dimensions are nominal

D (R-PDSO-G8)

PLASTIC SMALL OUTLINE

- NOTES:
- A. All linear dimensions are in inches (millimeters).
 - B. This drawing is subject to change without notice.
 - C. Body length does not include mold flash, protrusions, or gate burrs. Mold flash, protrusions, or gate burrs shall not exceed 0.006 (0,15) each side.
 - D. Body width does not include interlead flash. Interlead flash shall not exceed 0.017 (0,43) each side.
 - E. Reference JEDEC MS-012 variation AA.

D (R-PDSO-G8)

PLASTIC SMALL OUTLINE

4211283-2/E 08/12

- NOTES:
- A. All linear dimensions are in millimeters.
 - B. This drawing is subject to change without notice.
 - C. Publication IPC-7351 is recommended for alternate designs.
 - D. Laser cutting apertures with trapezoidal walls and also rounding corners will offer better paste release. Customers should contact their board assembly site for stencil design recommendations. Refer to IPC-7525 for other stencil recommendations.
 - E. Customers should contact their board fabrication site for solder mask tolerances between and around signal pads.

DBV (R-PDSO-G5)

PLASTIC SMALL-OUTLINE PACKAGE

- NOTES:
- A. All linear dimensions are in millimeters.
 - B. This drawing is subject to change without notice.
 - C. Body dimensions do not include mold flash or protrusion. Mold flash and protrusion shall not exceed 0.15 per side.
 - D. Falls within JEDEC MO-178 Variation AA.

DBV (R-PDSO-G5)

PLASTIC SMALL OUTLINE

- NOTES:
- A. All linear dimensions are in millimeters.
 - B. This drawing is subject to change without notice.
 - C. Customers should place a note on the circuit board fabrication drawing not to alter the center solder mask defined pad.
 - D. Publication IPC-7351 is recommended for alternate designs.
 - E. Laser cutting apertures with trapezoidal walls and also rounding corners will offer better paste release. Customers should contact their board assembly site for stencil design recommendations. Example stencil design based on a 50% volumetric metal load solder paste. Refer to IPC-7525 for other stencil recommendations.

IMPORTANT NOTICE

Texas Instruments Incorporated (TI) reserves the right to make corrections, enhancements, improvements and other changes to its semiconductor products and services per JESD46, latest issue, and to discontinue any product or service per JESD48, latest issue. Buyers should obtain the latest relevant information before placing orders and should verify that such information is current and complete.

TI's published terms of sale for semiconductor products (<http://www.ti.com/sc/docs/stdterms.htm>) apply to the sale of packaged integrated circuit products that TI has qualified and released to market. Additional terms may apply to the use or sale of other types of TI products and services.

Reproduction of significant portions of TI information in TI data sheets is permissible only if reproduction is without alteration and is accompanied by all associated warranties, conditions, limitations, and notices. TI is not responsible or liable for such reproduced documentation. Information of third parties may be subject to additional restrictions. Resale of TI products or services with statements different from or beyond the parameters stated by TI for that product or service voids all express and any implied warranties for the associated TI product or service and is an unfair and deceptive business practice. TI is not responsible or liable for any such statements.

Buyers and others who are developing systems that incorporate TI products (collectively, "Designers") understand and agree that Designers remain responsible for using their independent analysis, evaluation and judgment in designing their applications and that Designers have full and exclusive responsibility to assure the safety of Designers' applications and compliance of their applications (and of all TI products used in or for Designers' applications) with all applicable regulations, laws and other applicable requirements. Designer represents that, with respect to their applications, Designer has all the necessary expertise to create and implement safeguards that (1) anticipate dangerous consequences of failures, (2) monitor failures and their consequences, and (3) lessen the likelihood of failures that might cause harm and take appropriate actions. Designer agrees that prior to using or distributing any applications that include TI products, Designer will thoroughly test such applications and the functionality of such TI products as used in such applications.

TI's provision of technical, application or other design advice, quality characterization, reliability data or other services or information, including, but not limited to, reference designs and materials relating to evaluation modules, (collectively, "TI Resources") are intended to assist designers who are developing applications that incorporate TI products; by downloading, accessing or using TI Resources in any way, Designer (individually or, if Designer is acting on behalf of a company, Designer's company) agrees to use any particular TI Resource solely for this purpose and subject to the terms of this Notice.

TI's provision of TI Resources does not expand or otherwise alter TI's applicable published warranties or warranty disclaimers for TI products, and no additional obligations or liabilities arise from TI providing such TI Resources. TI reserves the right to make corrections, enhancements, improvements and other changes to its TI Resources. TI has not conducted any testing other than that specifically described in the published documentation for a particular TI Resource.

Designer is authorized to use, copy and modify any individual TI Resource only in connection with the development of applications that include the TI product(s) identified in such TI Resource. NO OTHER LICENSE, EXPRESS OR IMPLIED, BY ESTOPPEL OR OTHERWISE TO ANY OTHER TI INTELLECTUAL PROPERTY RIGHT, AND NO LICENSE TO ANY TECHNOLOGY OR INTELLECTUAL PROPERTY RIGHT OF TI OR ANY THIRD PARTY IS GRANTED HEREIN, including but not limited to any patent right, copyright, mask work right, or other intellectual property right relating to any combination, machine, or process in which TI products or services are used. Information regarding or referencing third-party products or services does not constitute a license to use such products or services, or a warranty or endorsement thereof. Use of TI Resources may require a license from a third party under the patents or other intellectual property of the third party, or a license from TI under the patents or other intellectual property of TI.

TI RESOURCES ARE PROVIDED "AS IS" AND WITH ALL FAULTS. TI DISCLAIMS ALL OTHER WARRANTIES OR REPRESENTATIONS, EXPRESS OR IMPLIED, REGARDING RESOURCES OR USE THEREOF, INCLUDING BUT NOT LIMITED TO ACCURACY OR COMPLETENESS, TITLE, ANY EPIDEMIC FAILURE WARRANTY AND ANY IMPLIED WARRANTIES OF MERCHANTABILITY, FITNESS FOR A PARTICULAR PURPOSE, AND NON-INFRINGEMENT OF ANY THIRD PARTY INTELLECTUAL PROPERTY RIGHTS. TI SHALL NOT BE LIABLE FOR AND SHALL NOT DEFEND OR INDEMNIFY DESIGNER AGAINST ANY CLAIM, INCLUDING BUT NOT LIMITED TO ANY INFRINGEMENT CLAIM THAT RELATES TO OR IS BASED ON ANY COMBINATION OF PRODUCTS EVEN IF DESCRIBED IN TI RESOURCES OR OTHERWISE. IN NO EVENT SHALL TI BE LIABLE FOR ANY ACTUAL, DIRECT, SPECIAL, COLLATERAL, INDIRECT, PUNITIVE, INCIDENTAL, CONSEQUENTIAL OR EXEMPLARY DAMAGES IN CONNECTION WITH OR ARISING OUT OF TI RESOURCES OR USE THEREOF, AND REGARDLESS OF WHETHER TI HAS BEEN ADVISED OF THE POSSIBILITY OF SUCH DAMAGES.

Unless TI has explicitly designated an individual product as meeting the requirements of a particular industry standard (e.g., ISO/TS 16949 and ISO 26262), TI is not responsible for any failure to meet such industry standard requirements.

Where TI specifically promotes products as facilitating functional safety or as compliant with industry functional safety standards, such products are intended to help enable customers to design and create their own applications that meet applicable functional safety standards and requirements. Using products in an application does not by itself establish any safety features in the application. Designers must ensure compliance with safety-related requirements and standards applicable to their applications. Designer may not use any TI products in life-critical medical equipment unless authorized officers of the parties have executed a special contract specifically governing such use. Life-critical medical equipment is medical equipment where failure of such equipment would cause serious bodily injury or death (e.g., life support, pacemakers, defibrillators, heart pumps, neurostimulators, and implantables). Such equipment includes, without limitation, all medical devices identified by the U.S. Food and Drug Administration as Class III devices and equivalent classifications outside the U.S.

TI may expressly designate certain products as completing a particular qualification (e.g., Q100, Military Grade, or Enhanced Product). Designers agree that it has the necessary expertise to select the product with the appropriate qualification designation for their applications and that proper product selection is at Designers' own risk. Designers are solely responsible for compliance with all legal and regulatory requirements in connection with such selection.

Designer will fully indemnify TI and its representatives against any damages, costs, losses, and/or liabilities arising out of Designer's non-compliance with the terms and provisions of this Notice.
